

## Chapter 16

# Innate Immunity: *The Host's Nonspecific Resistance Against Microbes*

# The Concept of Immunity

- **Immunity:** ability to ward off disease
- **Susceptibility:** host's lack of resistance to a disease
- **Innate immunity:** defenses against **any pathogen**  
// present at birth
- **Adaptive immunity:** is not present at birth /// must have "first contact" with pathogen to stimulate resistance /// results in resistance to a **specific** pathogen plus formation of **memory** cells activated upon second exposure

# Defenses Against Pathogens

---

- The human host has three lines of defense against pathogens
  - **first line of defense** // external barriers = Skin + mucous membranes /// this is called innate or non specific defenses
  - **second line of defense** – several nonspecific defense mechanisms // also called innate // 1<sup>st</sup> and 2<sup>nd</sup> are both non specific forms of resistance
    - leukocytes and macrophages, antimicrobial proteins, immune surveillance, inflammation, and fever
    - effective against a broad range of pathogens / but not any one specific type of pathogen!
  - **third line of defense** (the immune system) // defeats specific pathogens // after first exposure special ‘memory cells’ created which can be used to kill pathogen rapidly if a second exposure occurs in the future

## Overview of the body's defenses.

| Innate Immunity                                                                                                                           |                                                                                                                                                                                                            | Adaptive Immunity<br>(Chapter 17)                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| First line of defense                                                                                                                     | Second line of defense                                                                                                                                                                                     | Third line of defense                                                                                                                       |
| <ul style="list-style-type: none"><li>• Intact skin</li><li>• Mucous membranes and their secretions</li><li>• Normal microbiota</li></ul> | <ul style="list-style-type: none"><li>• Phagocytes, such as neutrophils, eosinophils, dendritic cells, and macrophages</li><li>• Inflammation</li><li>• Fever</li><li>• Antimicrobial substances</li></ul> | <ul style="list-style-type: none"><li>• Specialized lymphocytes: T cells and B cells</li><li>• Cellular response &amp; Antibodies</li></ul> |

## What is the difference between nonspecific resistance and immunity?

---

- **Non-specific resistance** (innate defenses) / First Two Lines of Defenses – physical barriers and innate defenses)
  - guards against a broad range of pathogens
  - their effectiveness does not depend on prior exposure
  - skin and mucous membranes
  - leukocytes and macrophages, antimicrobial proteins, immune surveillance, inflammation, and fever
- **Immunity** (acquired defenses) / Third Line of Defense
  - Specificity - recognition of pathogen
  - Memory – rapid response after first exposure
  - Humoral and cellular response / tagged vs killed!
  - Able to learn from prior exposure so faster response for a second exposure to same pathogen (ie. memory)
  - The three “R”s of immunity: recognize / react / remember

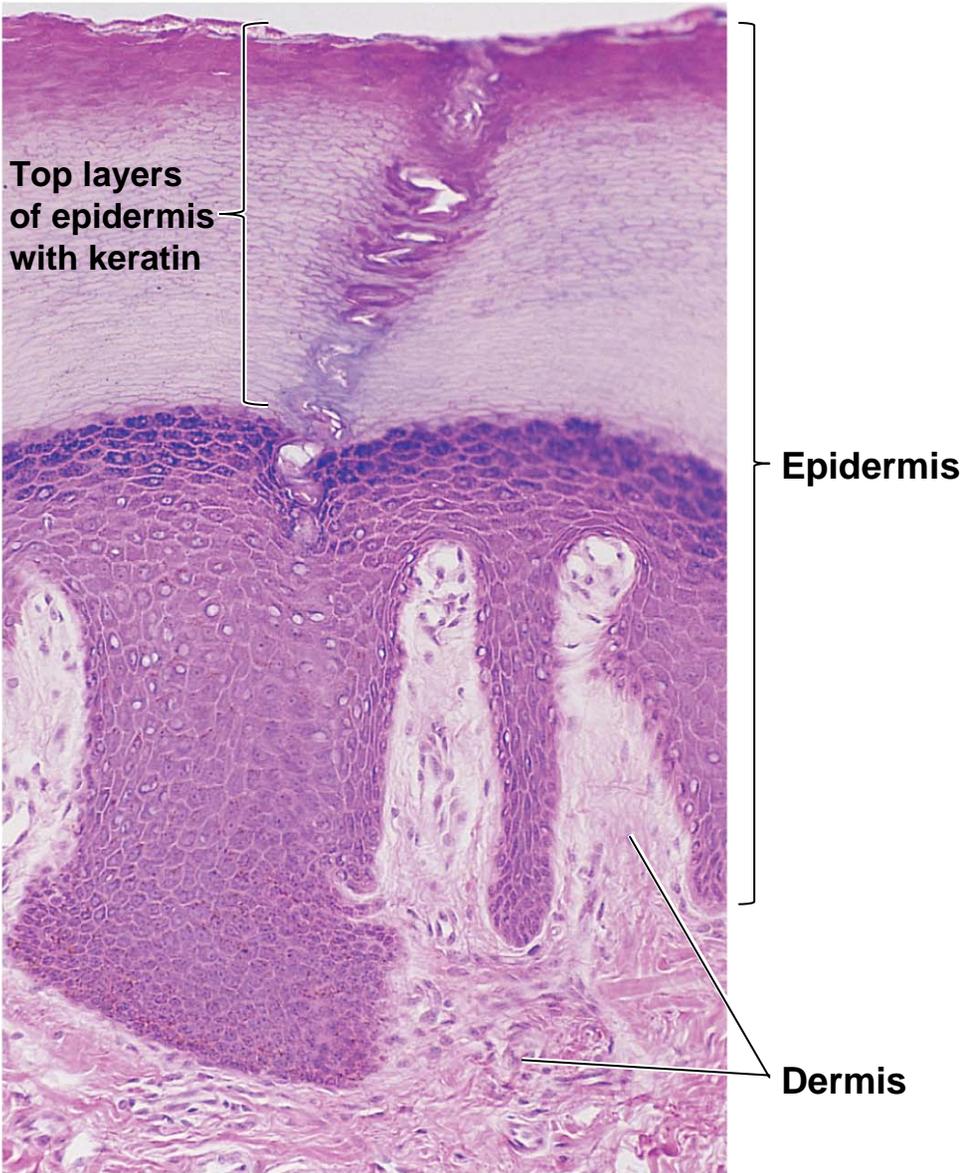

# Factors used by Innate Immunity

- **Transferrins** // Designed to keep iron away from bacteria – iron essential growth factor for bacteria // Bind serum iron when in blood // ferritin – binds and stores iron in liver
  - Note: Siderophores produced by bacteria to “capture” iron from host // considered a community good for bacteria!
- **Antimicrobial peptides** // secreted onto surface of skin // Lyses bacterial cells – e.g. defensins

# Physical Factors Used in Innate Immunity

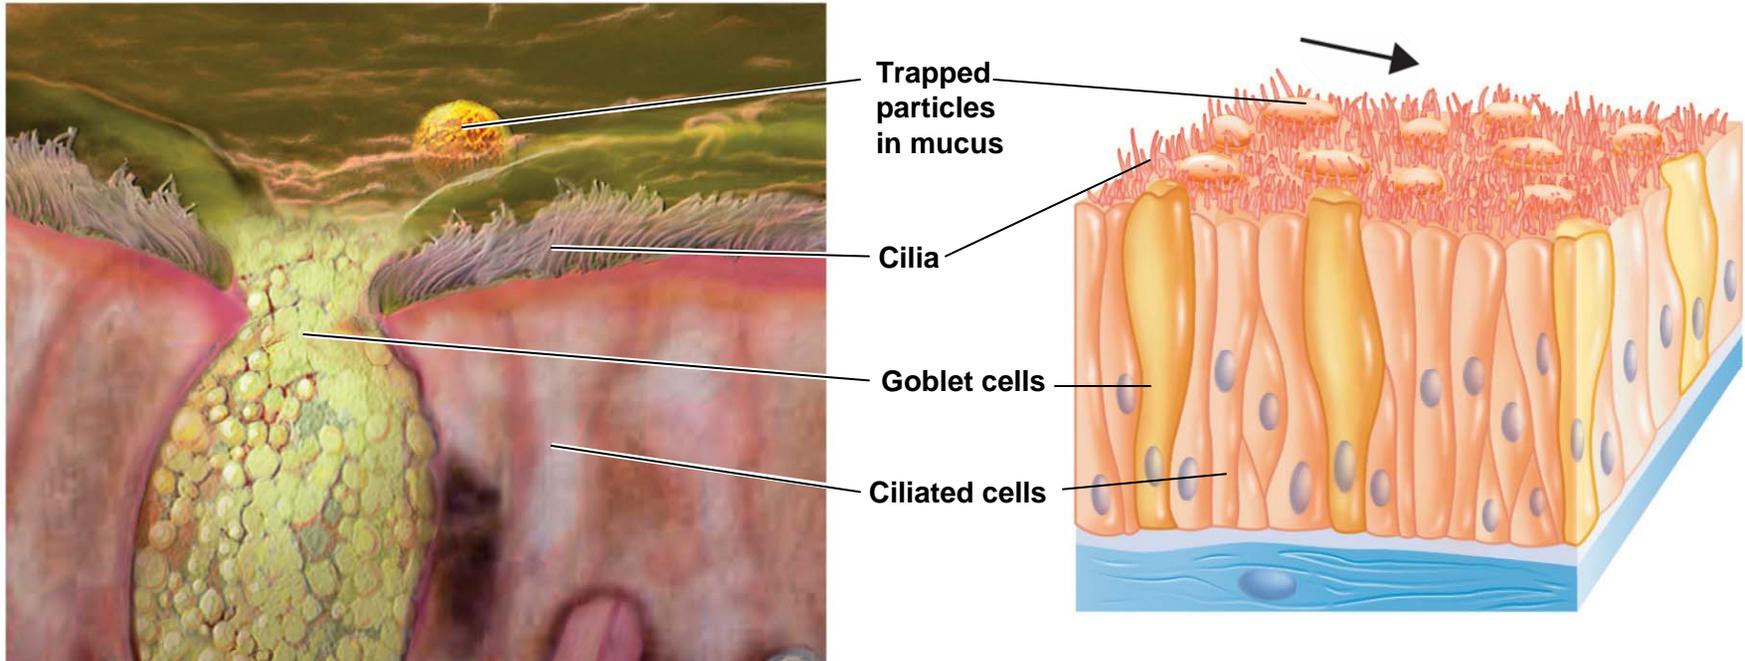

- **Skin** – dry and acidic / antimicrobial proteins like defensins
- **Epidermis** - consists of tightly packed cells with // **Keratin**, a protective protein

**A section through human skin.**

LM 30 μm

## The ciliary escalator.

Computer-enhanced SEM | 10  $\mu\text{m}$

# Fever

## ■ Advantages

- Increases transferrins
- Increases IL-1 activity
- Produces interferon
- Fever moves free iron into liver so bacteria denied iron

## ■ Disadvantages

- Tachycardia
- Acidosis
- Dehydration
- 44–46°C fatal

# How Fever Works

- Abnormally high body temperature
- Hypothalamus is normally set at 37°C
- Pyrogens // endogenous vs exogenous // released by neutrophils and bacteria
- Gram-negative endotoxins cause phagocytes to release interleukin-1 (IL-1)
- Hypothalamus releases prostaglandins that reset the hypothalamus to a high temperature
- Body increases rate of metabolism, and **shivering** occurs, which raise temperature
- Vasodilation and sweating: body temperature falls (**crisis**)

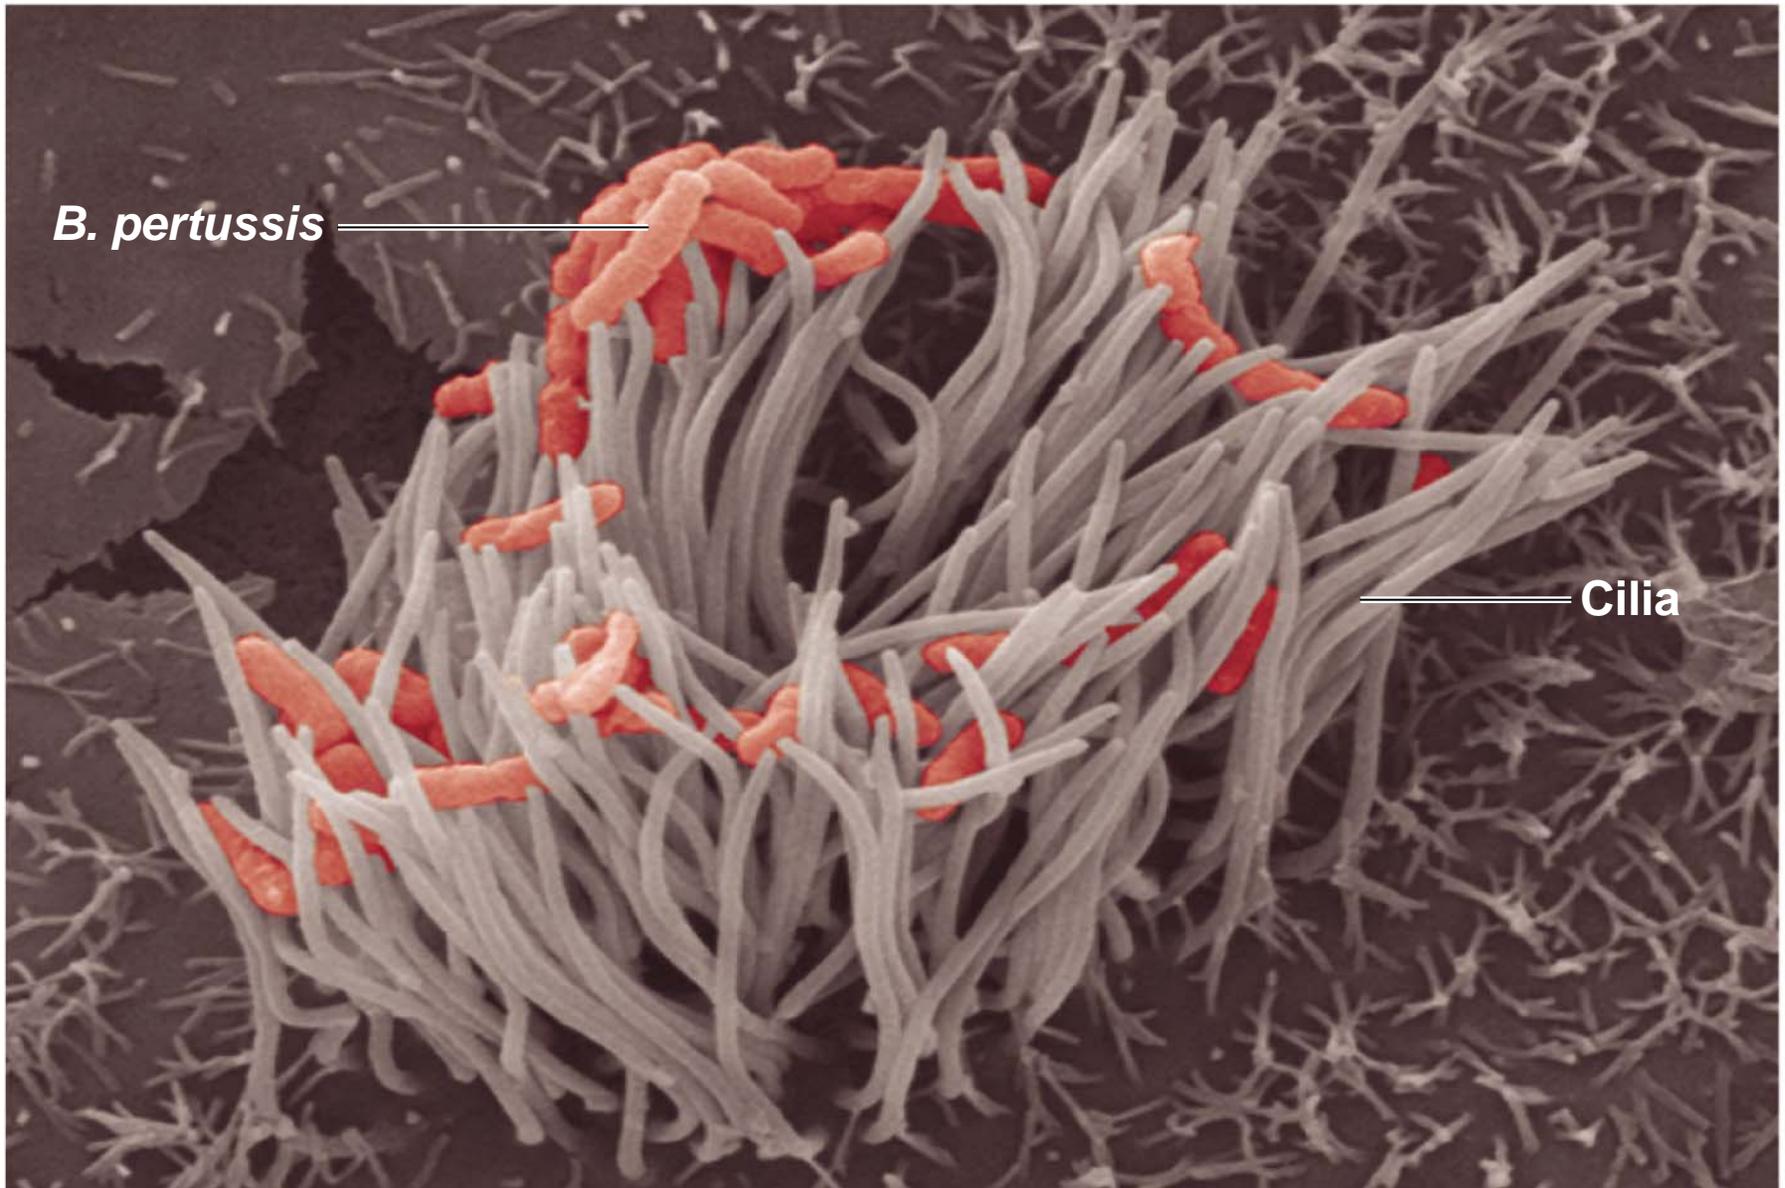

# PAMPs & TLRs in Innate Immunity

- Host cells (e.g. macrophage) have **Toll-like receptors (TLRs) on their plasma membranes**
- **All microbes have some similar surface macromolecules = pathogen-associated molecular patterns (PAMPs) that can bind to TLRs**
- TLRs induce macrophage to release **cytokines** that regulate the intensity and duration of immune responses

# Physical Factors

- **Mucous membranes**
- **Mucus:** traps microbes
- **Ciliary escalator:** transports microbes trapped in mucus away from the lungs

Ciliated cells of the respiratory system infected with *Bordetella pertussis*.

SEM

2  $\mu$ m

# Physical Factors

- **Lacrimal apparatus:** washes eye
- **Saliva:** washes microbes off
- **Urine:** flows out
- **Vaginal secretions:** flow out

## The lacrimal apparatus.

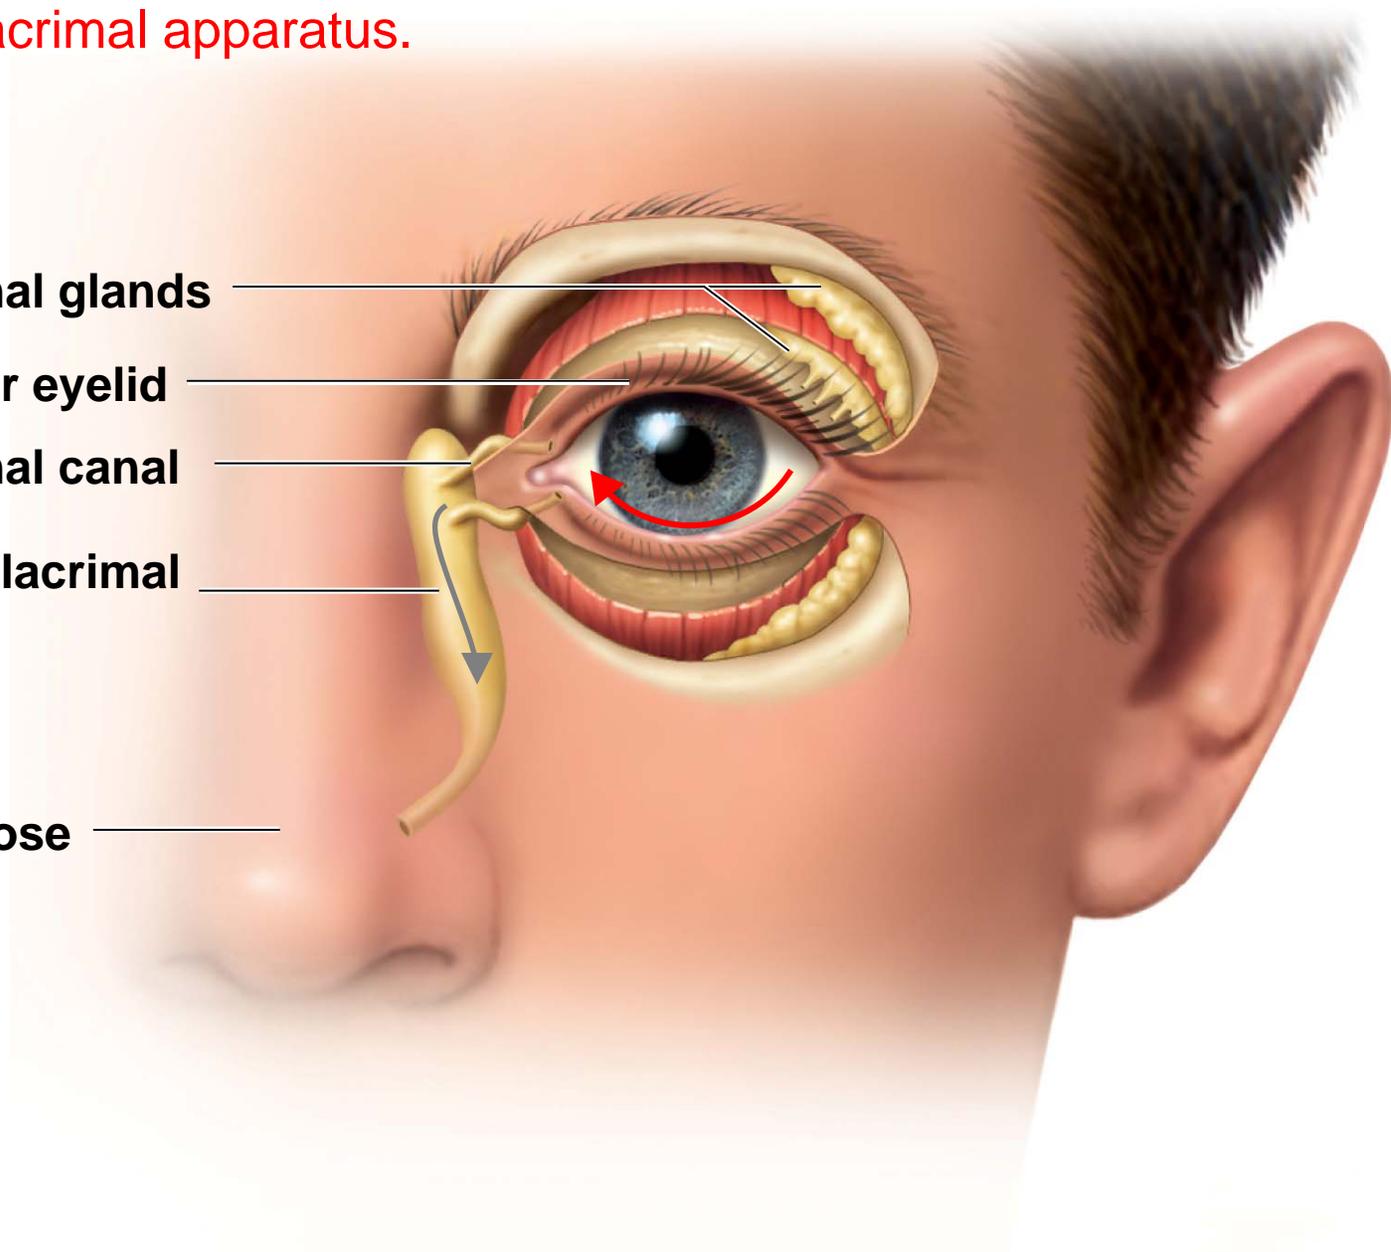

Lacrimal glands

Upper eyelid

Lacrimal canal

Nasolacrimal  
duct

Nose

# Chemical Factors by Host Cells

- Fungistatic fatty acids in sebum
- Low pH (3–5) of skin
- Lysozyme in perspiration, tears, saliva, and urine // breaks down peptidoglycan of cell wall // same action as penicillin
- Low pH (1.2–3.0) of gastric juice // kills bacteria
- Low pH (3–5) of vaginal secretions // epithelial cells secrete glycogen – *Lactobacillus acidophilus* metabolize sugar and secrete lactic acid – inhibits *Candida albicans* (i.e. fungal infections)

# Normal Microbiota and Innate Immunity

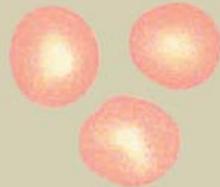

- **Microbial antagonism = competitive exclusion**
- **Normal microbiota** compete with pathogens for space and resources // or alter the environment to resist pathogens by secreting antimicrobial molecules (e.g. bacteriocidins)
  - Note: the normal microbiota may at a later time may become an opportunistic pathogens
- **Commensal microbiota:** one organism (microbe) benefits, while the host is unharmed

# Formed Elements in Blood (Part 1 of 2)

TABLE 16.1 Formed Elements in Blood

## I. Erythrocytes (Red Blood Cells)

4.8–5.4 million per  $\mu\text{l}$  or  $\text{mm}^3$   
Function: Transport of  $\text{O}_2$  and  $\text{CO}_2$

LM 4  $\mu\text{m}$

## II. Leukocytes (White Blood Cells)

5000–10,000 per  $\mu\text{l}$  or  $\text{mm}^3$

### A. Granulocytes (stained)

1. Neutrophils (PMNs)  
(60–70% of leukocytes)  
Function: Phagocytosis

LM 4  $\mu\text{m}$

2. Basophils (0.5–1%)  
Function: Production of histamine

LM 3  $\mu\text{m}$

### B. Agranulocytes (stained)

1. Monocytes (3–8%)  
Function: Phagocytosis  
(when they mature into macrophages)

LM 5  $\mu\text{m}$

LM 10  $\mu\text{m}$

2. Dendritic cells  
Functions: Derived from monocytes; phagocytosis and initiation of adaptive immune responses

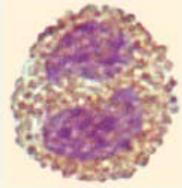

LM 10  $\mu\text{m}$

## Formed Elements in Blood (Part 2 of 2)

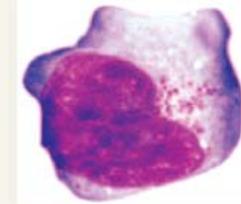

TABLE 16.1 Formed Elements in Blood

3. Eosinophils (2–4%)  
Functions: Production of toxic proteins against certain parasites; some phagocytosis

LM 4  $\mu\text{m}$

3. Lymphocytes (20–25%)  
• Natural killer (NK) cells  
Function: Destroy target cells by cytolysis and apoptosis

LM 2.5  $\mu\text{m}$

• T cells  
Function: Cell-mediated immunity (discussed in Chapter 17)

LM 15  $\mu\text{m}$

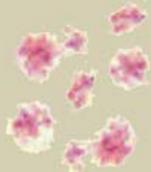

• B cells  
Function: Descendants of B cells (plasma cells) produce antibodies

LM 8  $\mu\text{m}$

### III. Platelets

150,000–400,000 per  $\mu\text{l}$  or  $\text{mm}^3$   
Function: Blood clotting

LM 2.5  $\mu\text{m}$

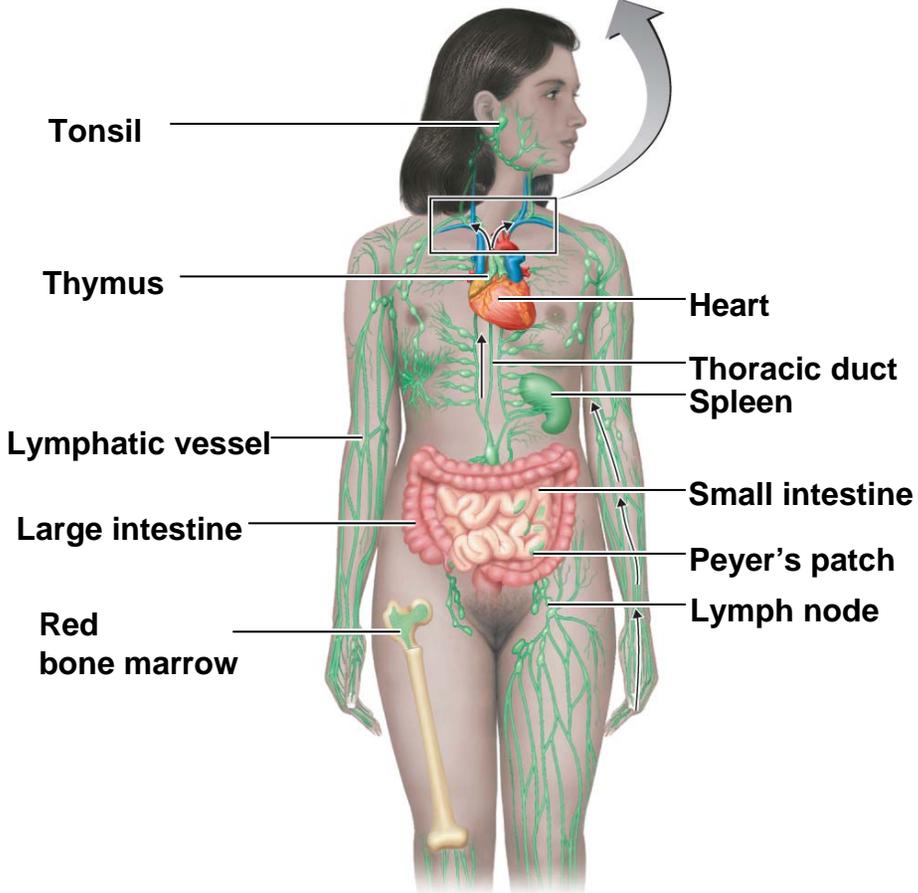

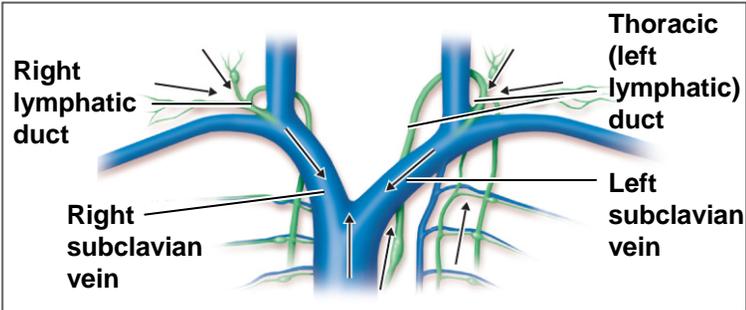

# Differential White Cell Count

- Percentage of each type of white cell in a sample of 100 white blood cells

|                    |        |
|--------------------|--------|
| <b>Neutrophils</b> | 60–70% |
| <b>Basophils</b>   | 0.5–1% |
| <b>Eosinophils</b> | 2–4%   |
| <b>Monocytes</b>   | 3–8%   |
| <b>Lymphocytes</b> | 20–25% |

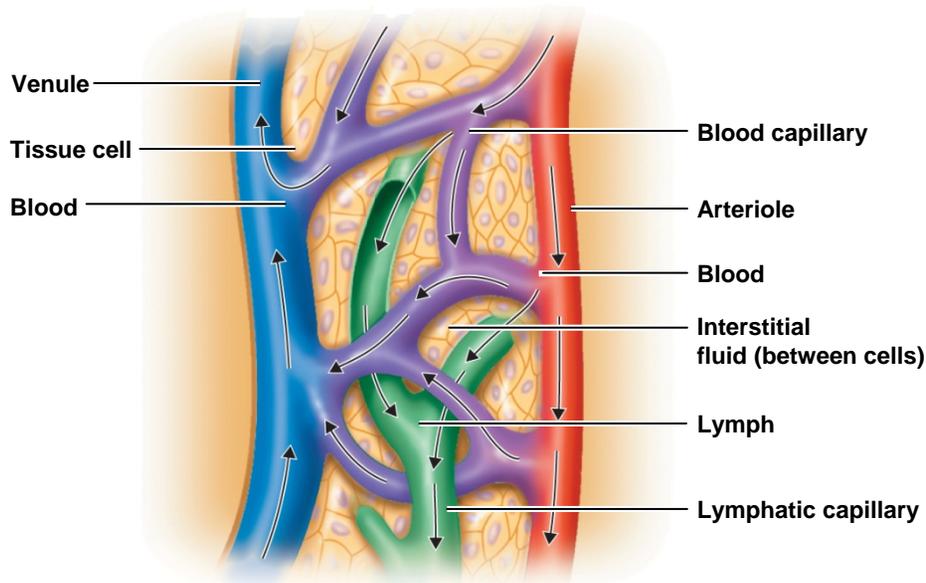

Never let monkeys eat bananas!

# The lymphatic system.

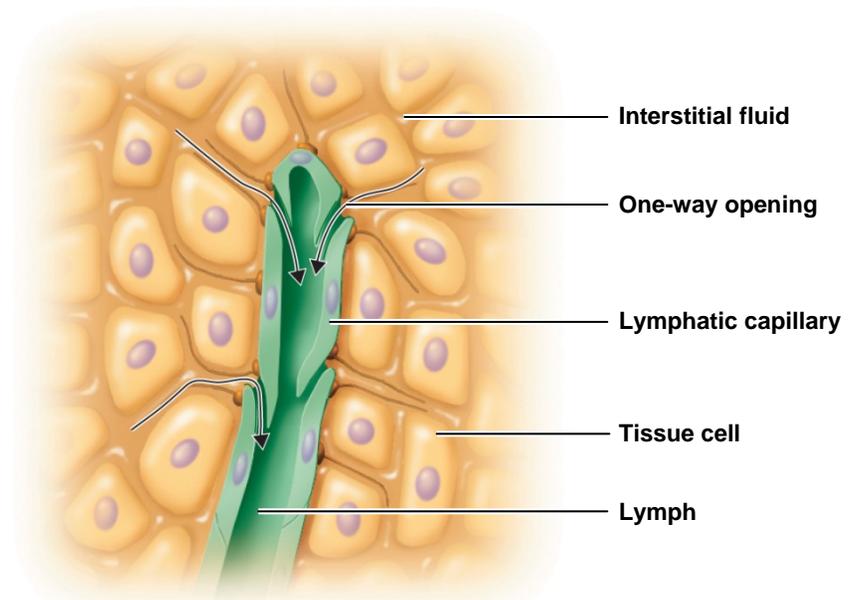

(a) Components of lymphatic system

# The lymphatic system.

**(b) Relationship of lymphatic capillaries to tissue cells and blood capillaries**

**(c) Details of a lymphatic capillary**

Note: lymph nodes functions / filter & germination center for active immunity

# Phagocytosis – Key Factor in Innate Immunity

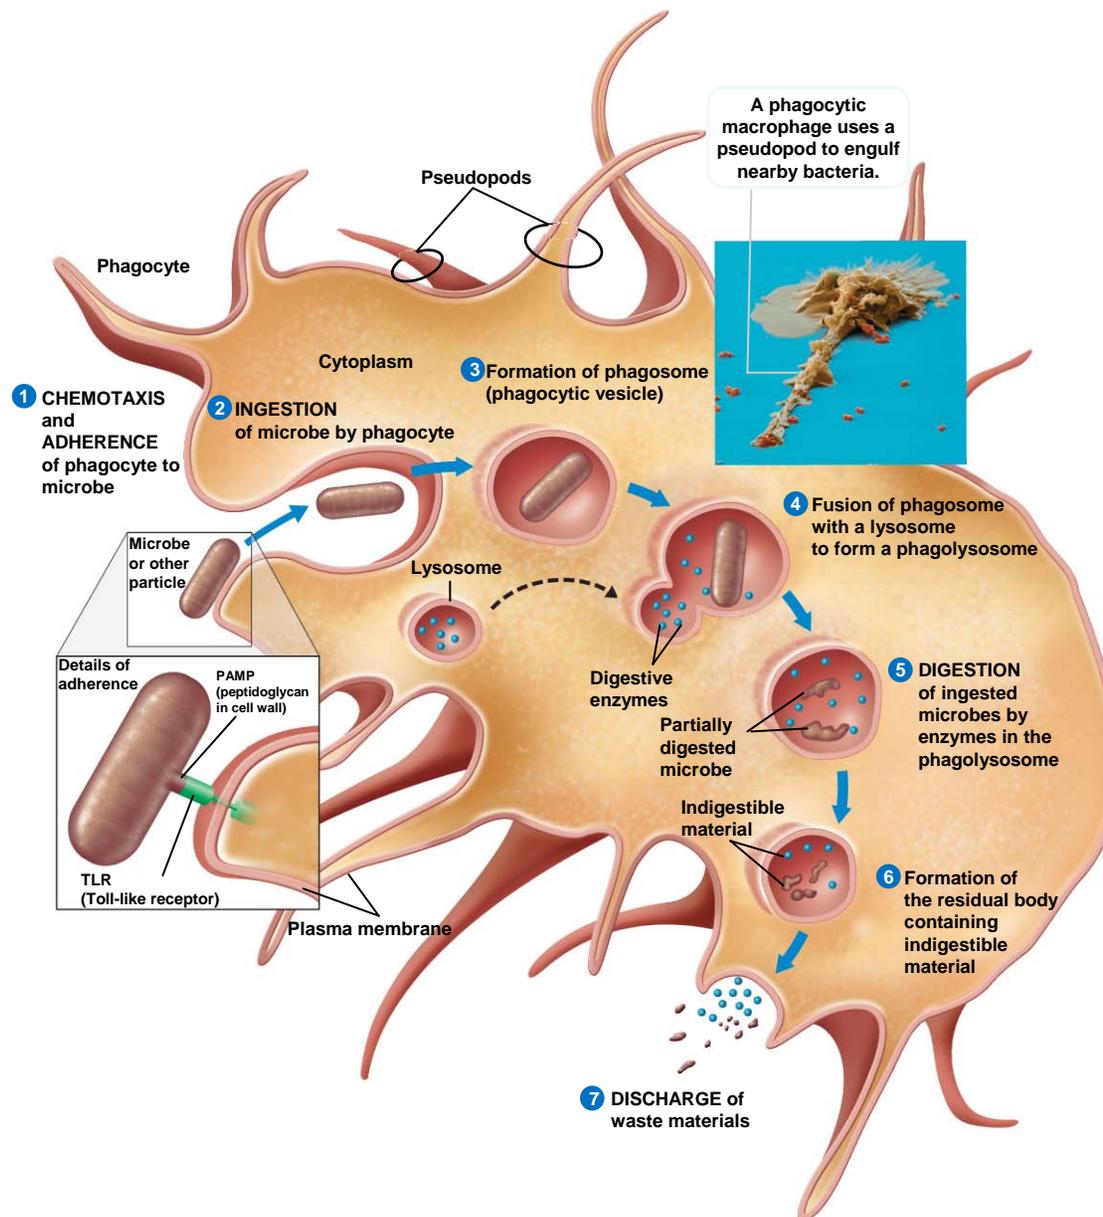

- *Phago*: from Greek, meaning eat
- *Cyte*: from Greek, meaning cell
- Ingestion of microbes or particles by a cell, performed by phagocytes
- Macrophage are the most active of all phagocytic cells

# Cells Capable of Phagocytosis

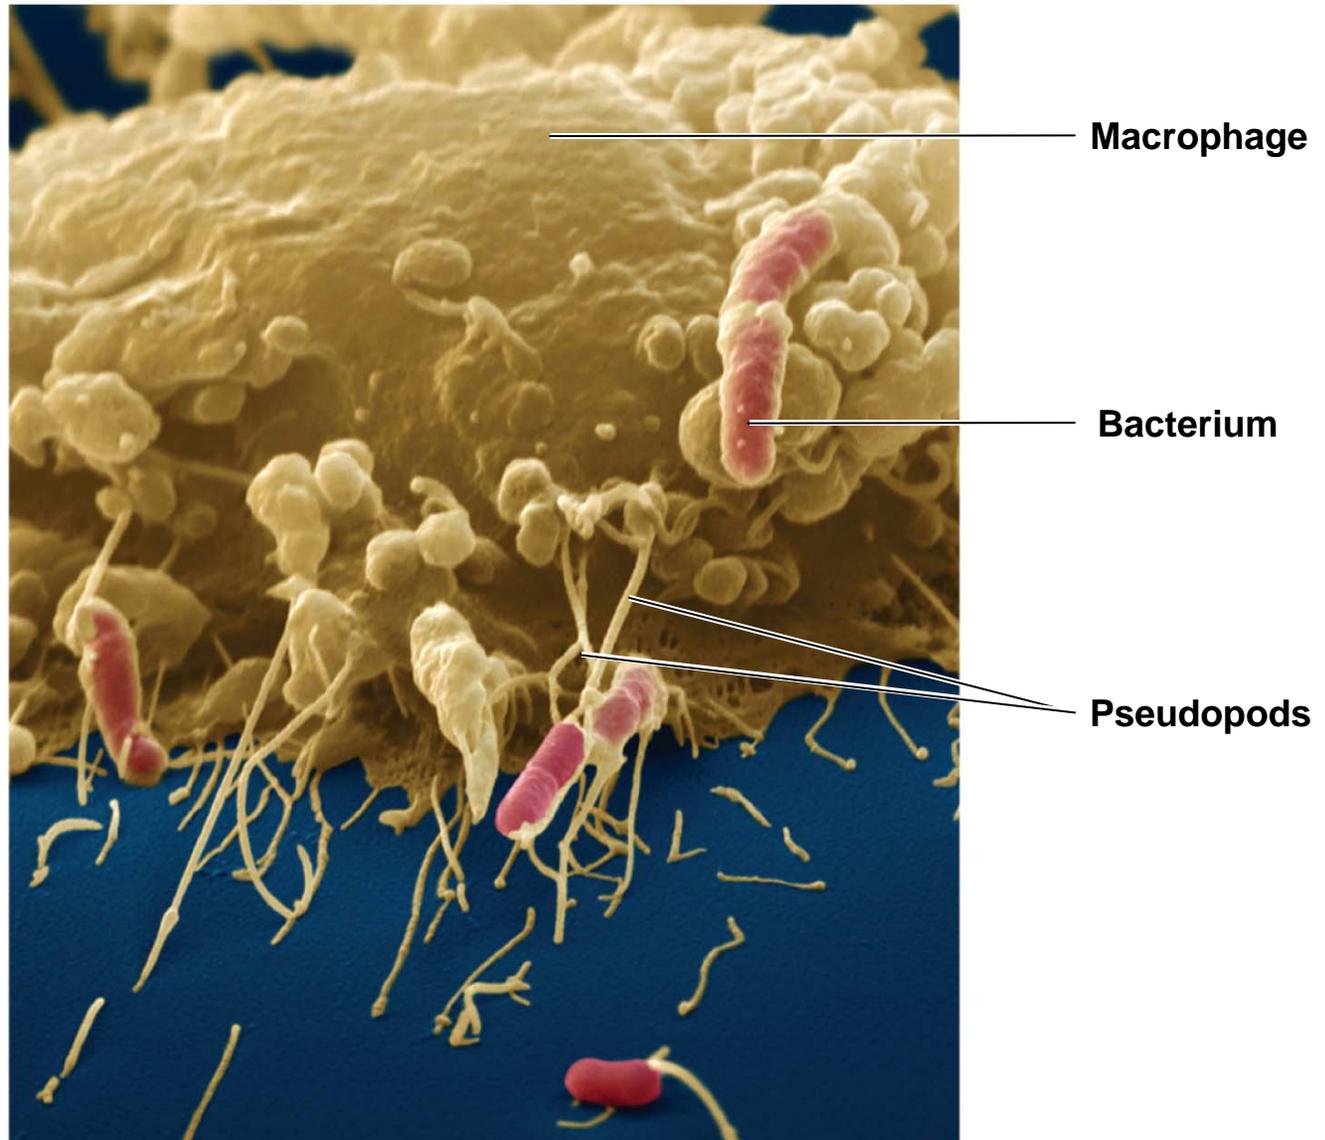

- **Neutrophils**
- **Fixed macrophages**
- **Wandering macrophages**

Note: other cells are also able to engulf particles // this is not a complete list.

# The Phases of Phagocytosis.

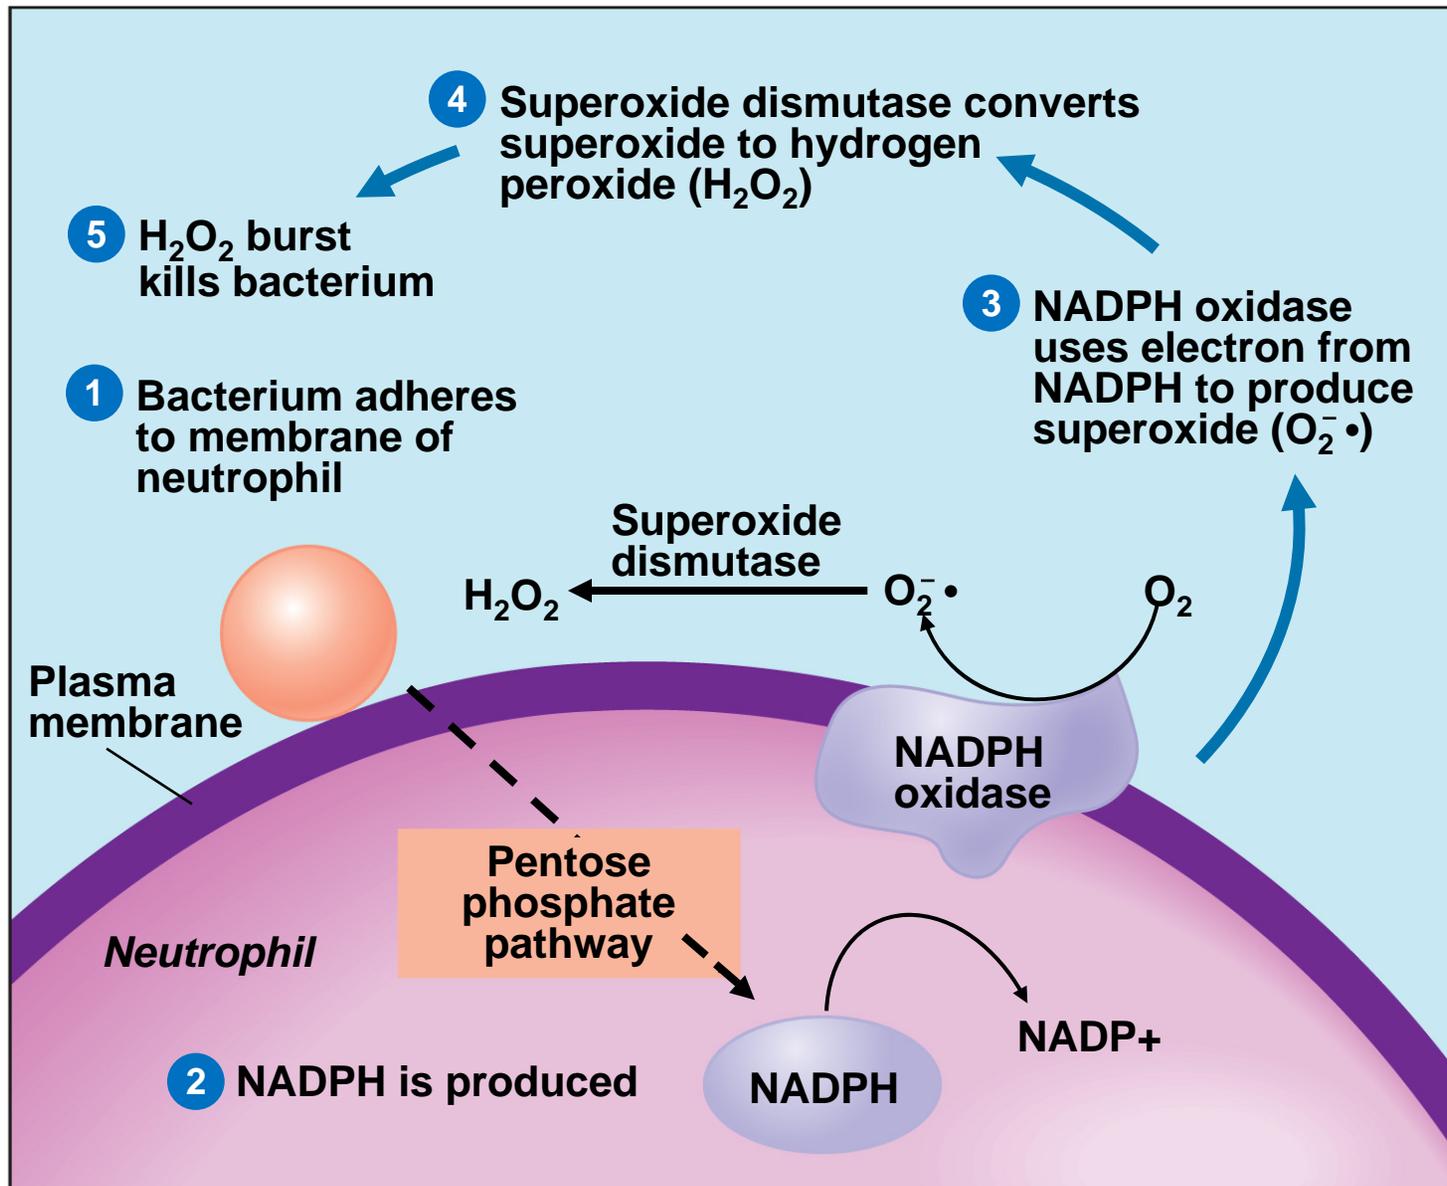

# A macrophage engulfing rod-shaped bacteria.

SEM | 2.5  $\mu\text{m}$

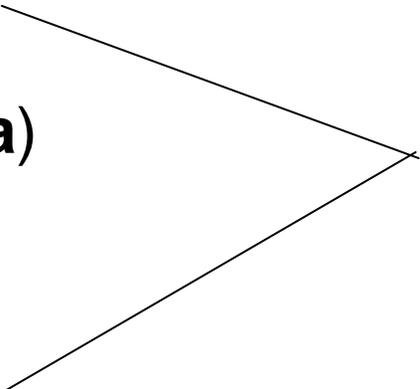

# Oxidative Burst (Neutrophils & Eosinophils)

## How Microbes Evade Destruction by Phagocytosis

|                                             |                                                      |
|---------------------------------------------|------------------------------------------------------|
| Inhibit adherence:<br>M protein, capsules   | <i>Streptococcus pyogenes</i> , <i>S. pneumoniae</i> |
| Kill phagocytes: Leukocidins                | <i>Staphylococcus aureus</i>                         |
| Lyse phagocytes:<br>Membrane attack complex | <i>Listeria monocytogenes</i>                        |
| Escape phagosome                            | <i>Shigella</i> , <i>Rickettsia</i>                  |
| Prevent phagosome–<br>lysosome fusion       | HIV, <i>Mycobacterium tuberculosis</i>               |
| Survive in phagolysosome                    | <i>Coxiella burnettii</i>                            |

# Inflammation

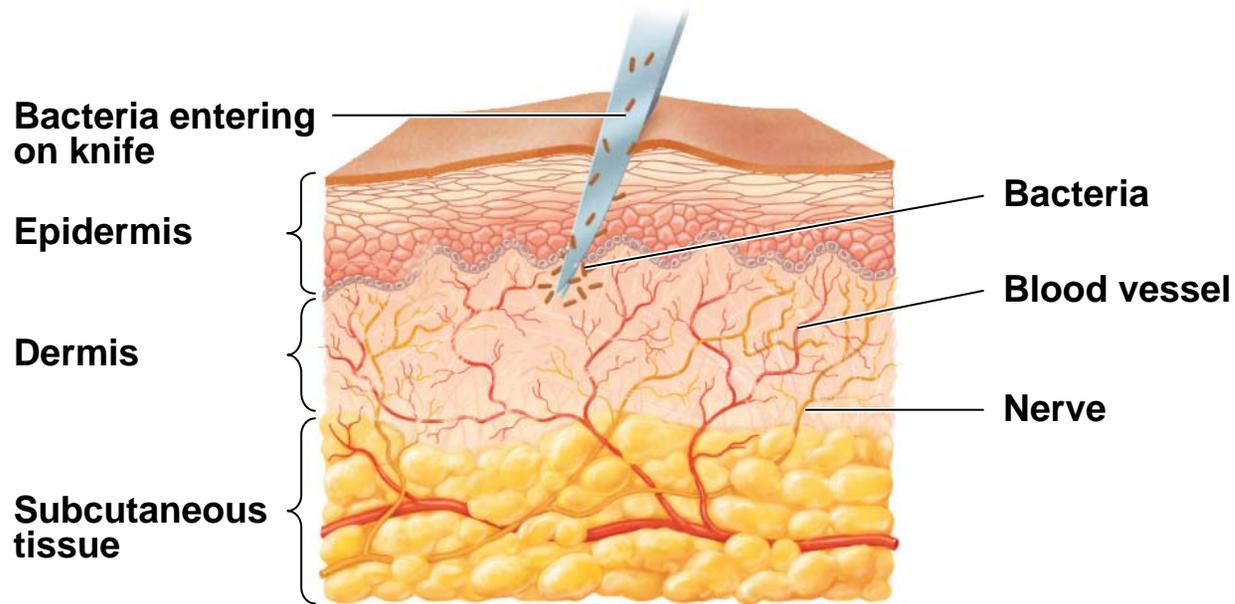

- Response to tissue injury // regardless of cause
  - Activation of **acute-phase proteins** (complement, cytokine, and kinins)
  - **First step is vasodilation** (caused by histamine, kinins, prostaglandins, and leukotrienes) – results in .....
- 
- Redness
  - Swelling (**edema**)
  - Pain
  - Heat
- 
- The Cardinal Signs  
of Inflammation

# Chemicals Released by Damaged Cells

|                       |                                                                |
|-----------------------|----------------------------------------------------------------|
| <b>Histamine</b>      | Vasodilation, increased permeability of blood vessels          |
| <b>Kinins</b>         | Vasodilation, increased permeability of blood vessels          |
| <b>Prostaglandins</b> | Intensify histamine and kinin effect                           |
| <b>Leukotrienes</b>   | Increased permeability of blood vessels, phagocytic attachment |

Note: aspirin reduces inflammation by lowering prostaglandins production

## The process of inflammation.

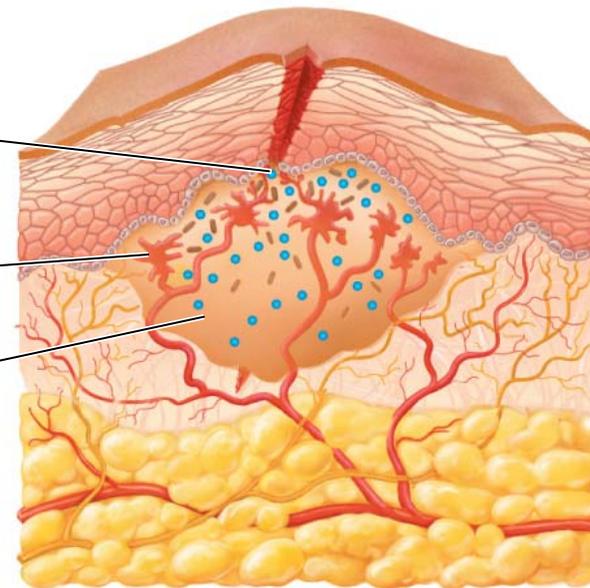

(a) Tissue damage

**1** Chemicals such as histamine, kinins, prostaglandins, leukotrienes, and cytokines (represented as blue dots) are released by damaged cells.

**2** Blood clot forms.

**3** Abscess starts to form (orange area).

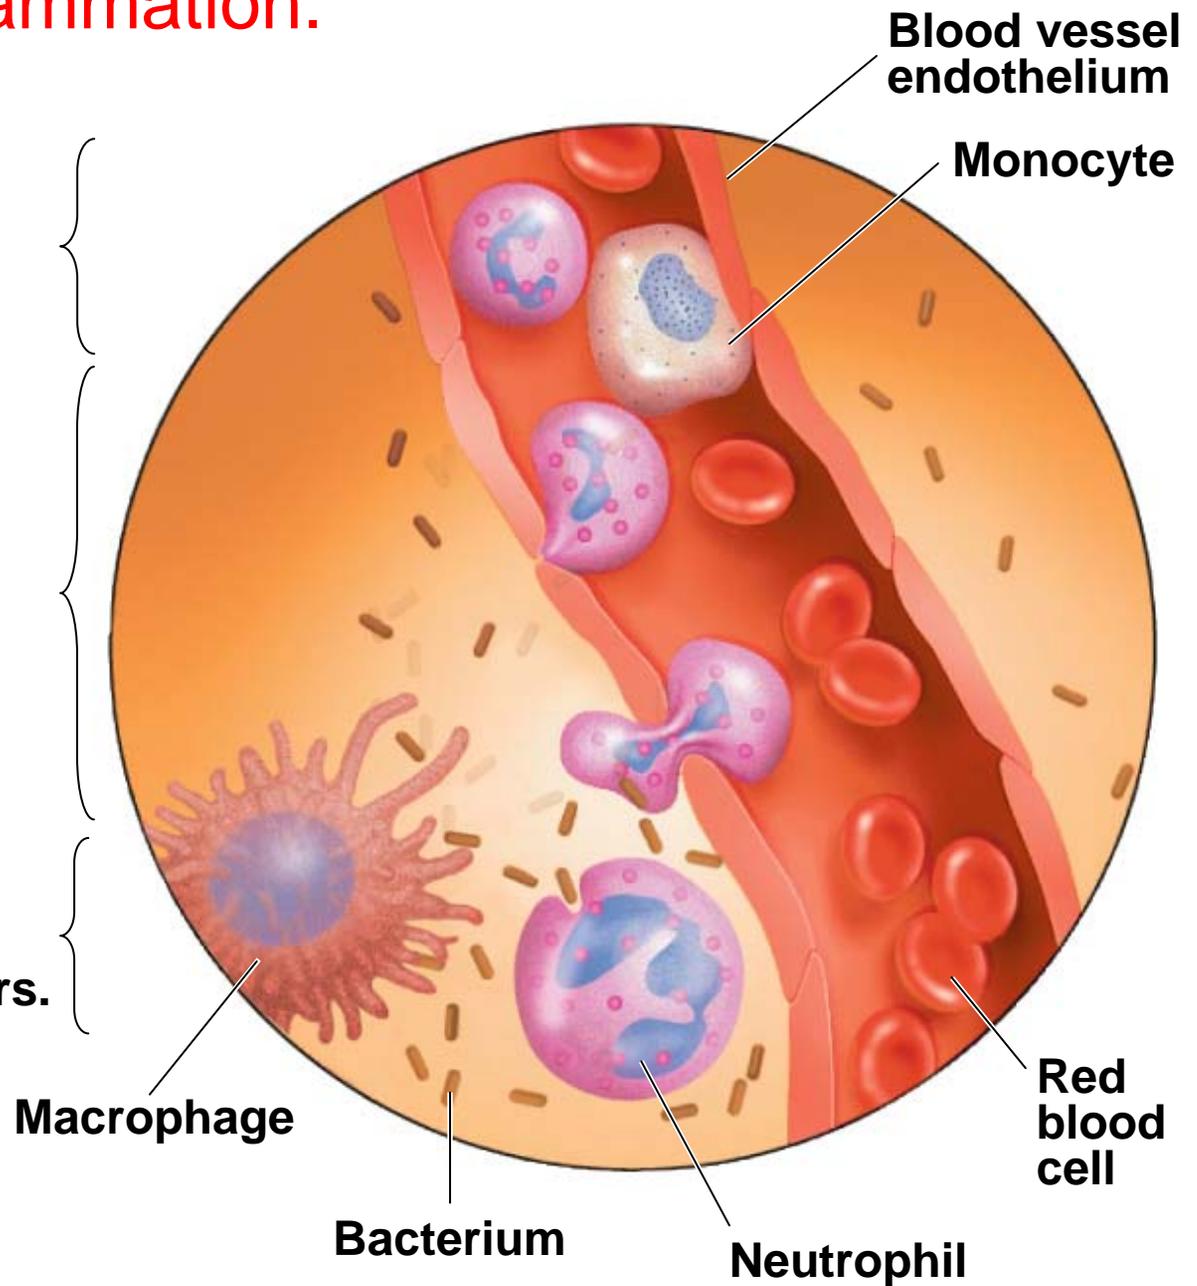

(b) Vasodilation and increased permeability of blood vessels

# The process of inflammation.

**4** Margination—  
phagocytes stick  
to endothelium.

**5** Diapedesis—  
phagocytes  
squeeze  
between  
endothelial cells.

**6** Phagocytosis of  
invading bacteria occurs.

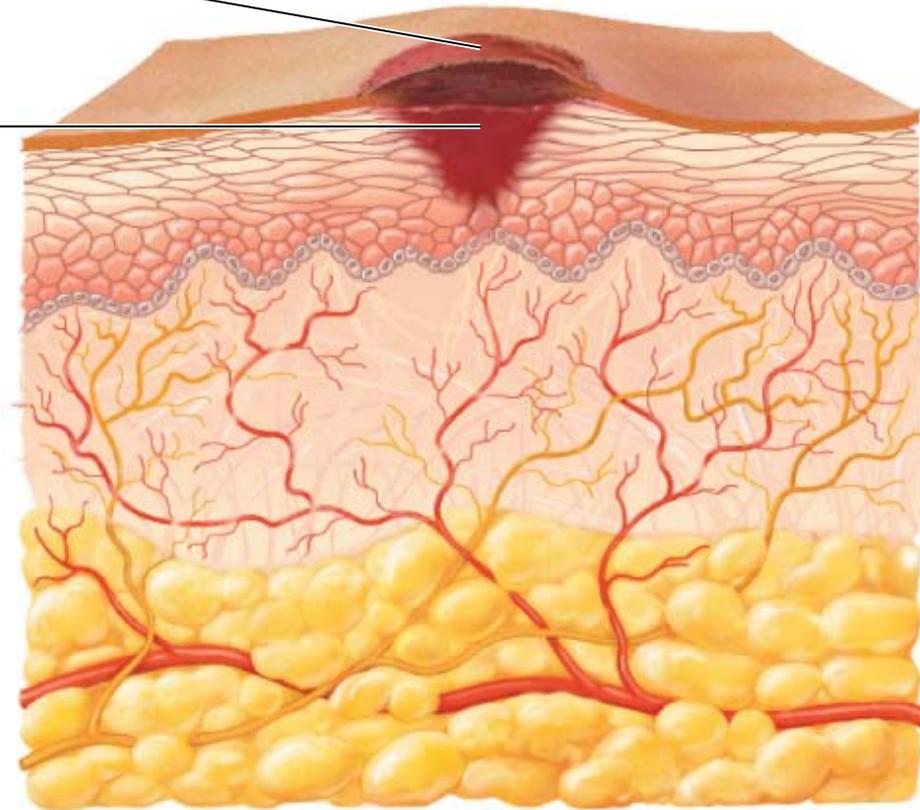

(C) Phagocyte migration  
and phagocytosis

# The process of inflammation.

Scab

Blood clot

Regenerated  
epidermis  
(parenchyma)

Regenerated  
dermis  
(stroma)

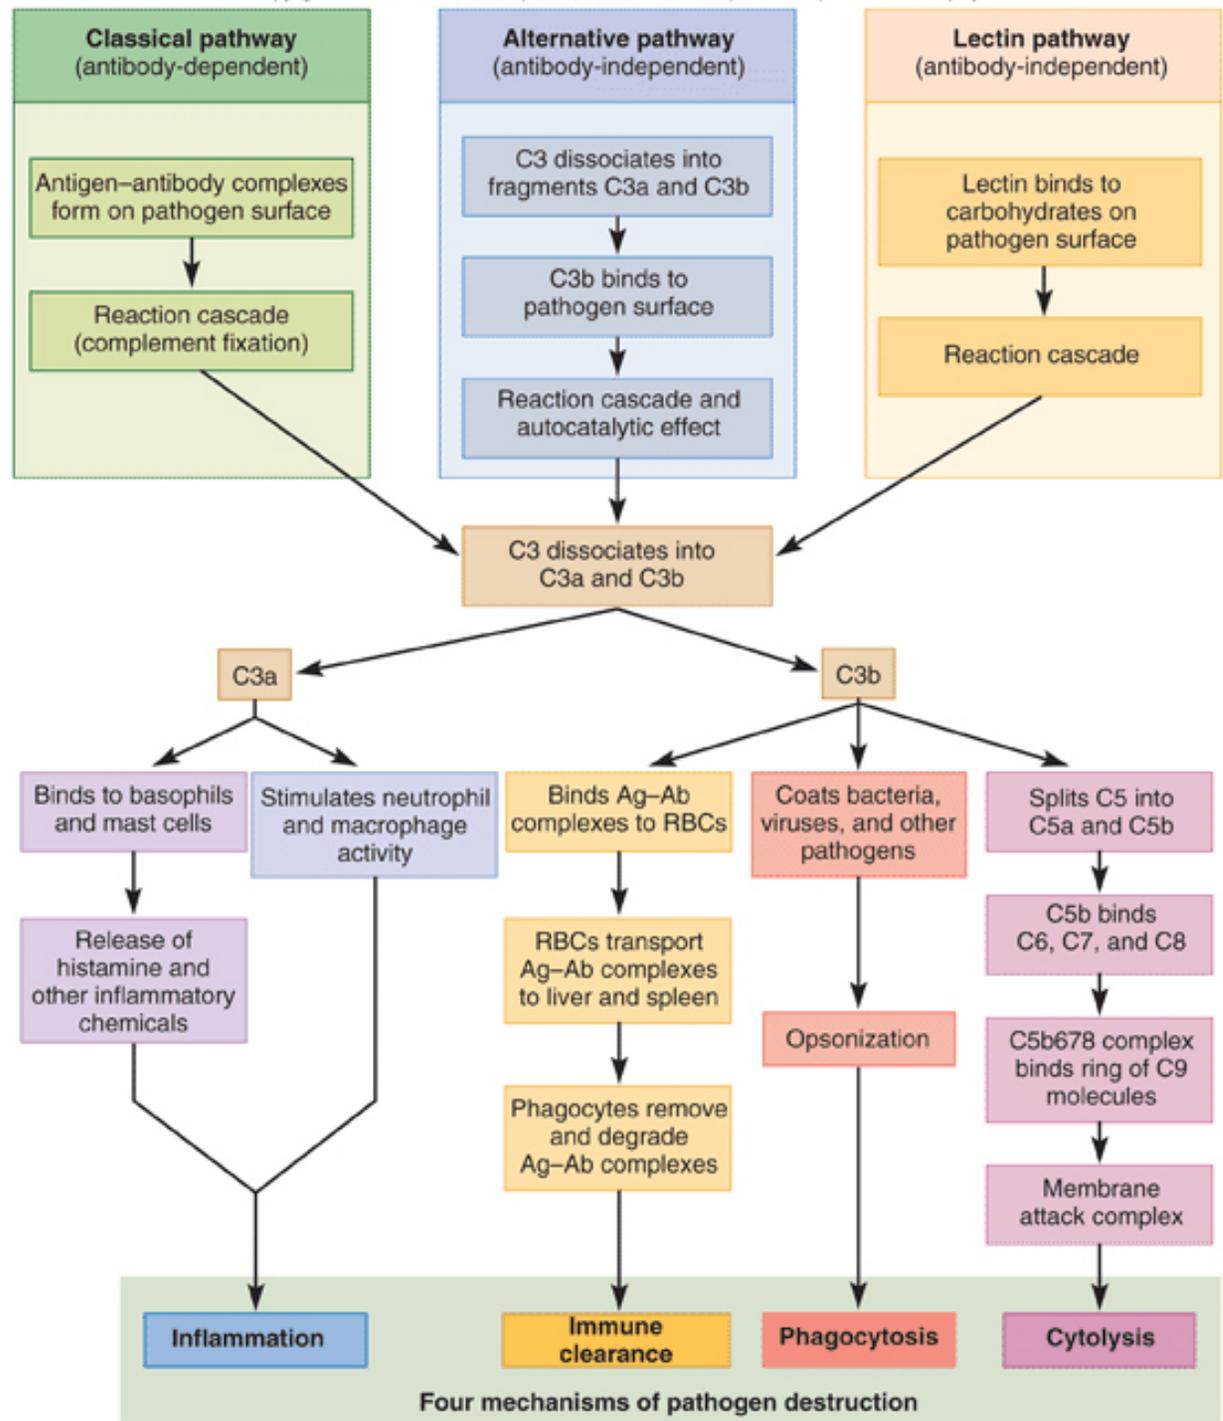

(d) **Tissue repair**

Note: Regeneration vs Fibrosis // tissue damage always results in certain amount of new additional extracellular fiber

# The Complement System

- Serum proteins made by liver
- Circulates as “inactive” plasma proteins
- Activated in a cascade fashion / positive feedback
- Activation occurs by three different pathways

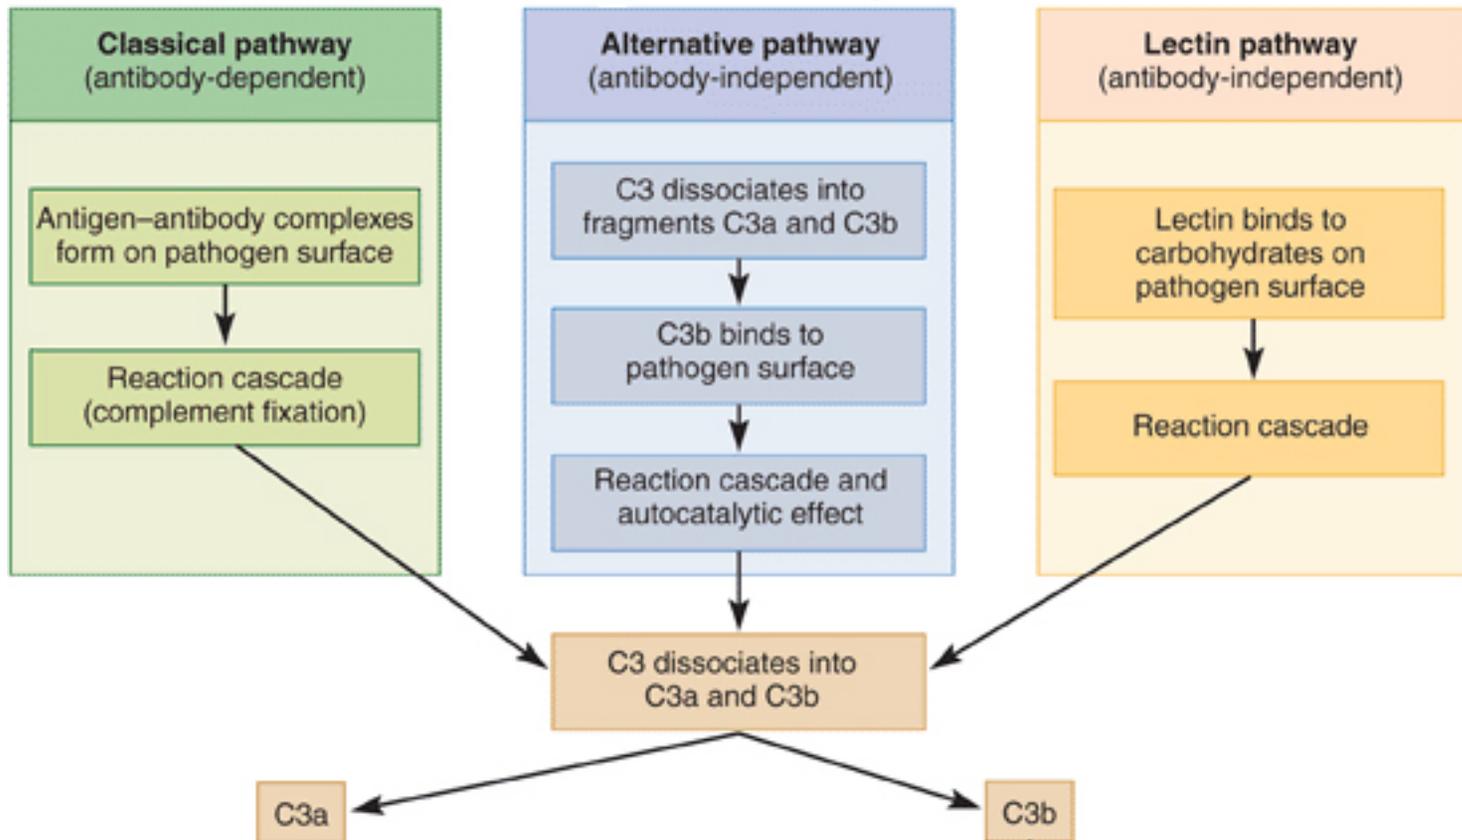

# Complement Activation

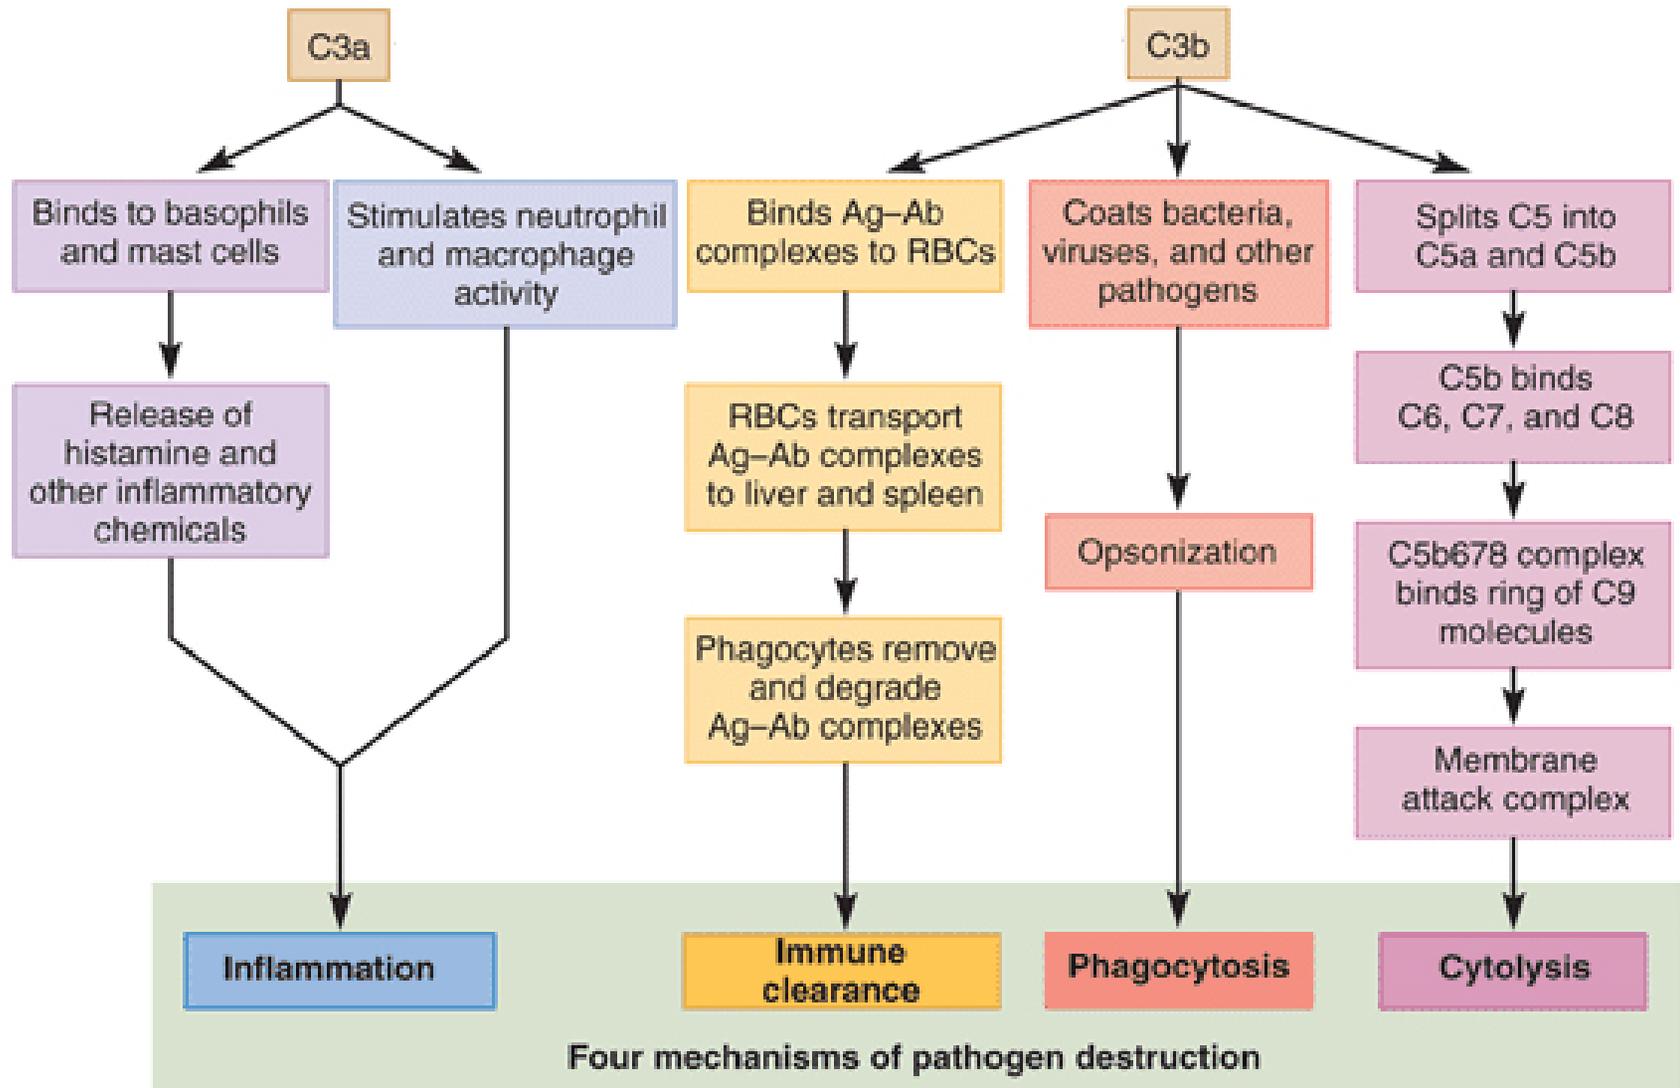

# This is how complement is activated. (Three Options)

This pathway is part of specific immunity because it depends on the B Cells / plasma cells antibodies.

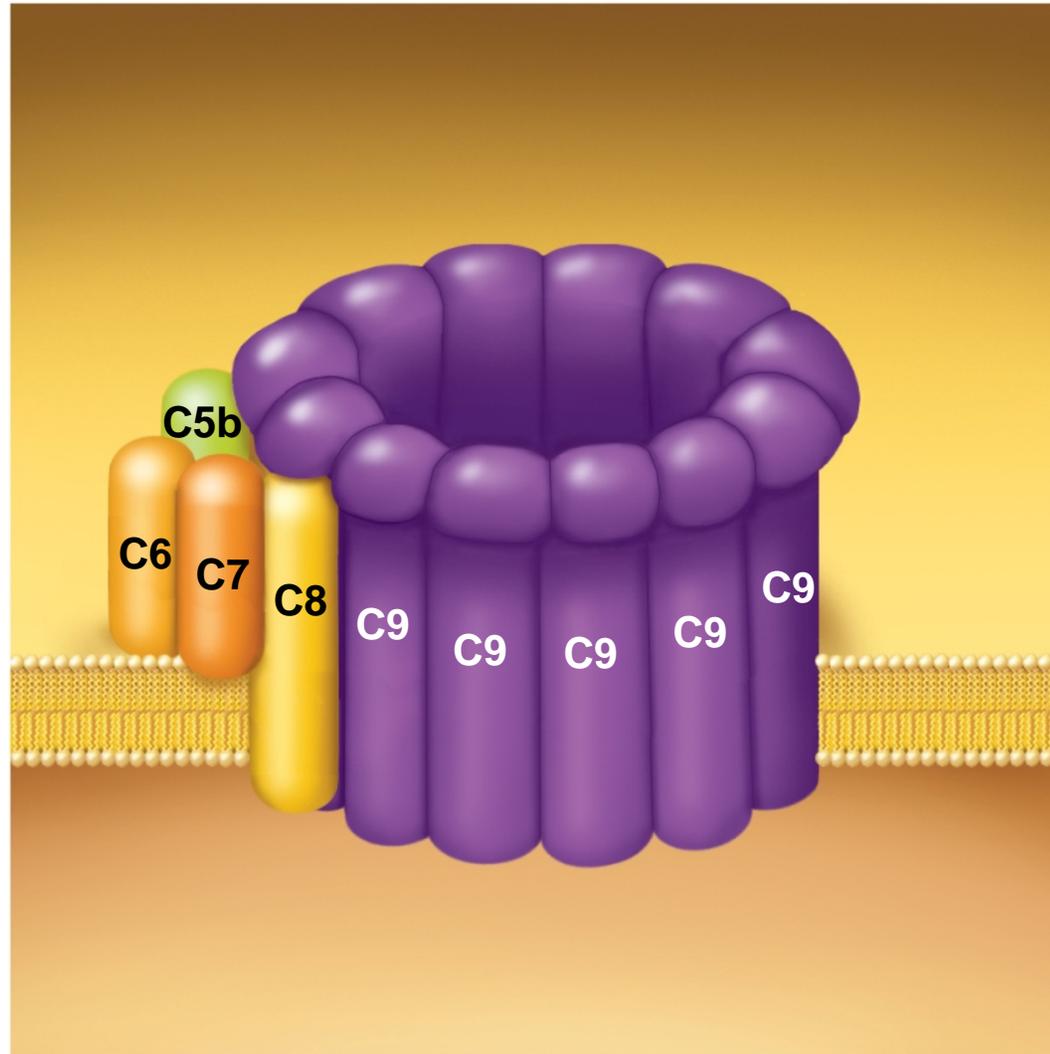

These pathways are part of the non specific resistance because they function independent of the B and T cells.

Complement's outcomes are a mixture of non-specific resistance and immunity:

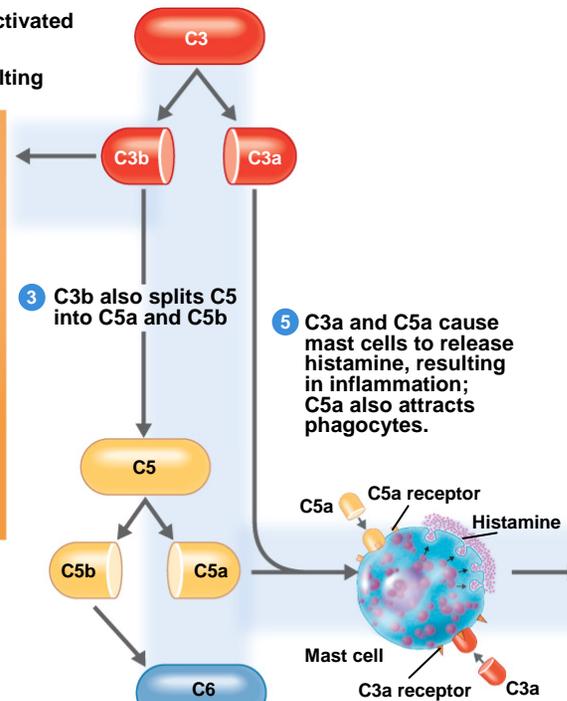

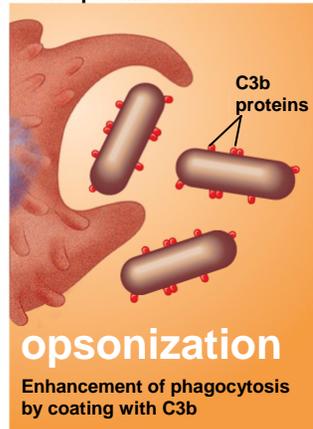

# Membrane Attack Complex

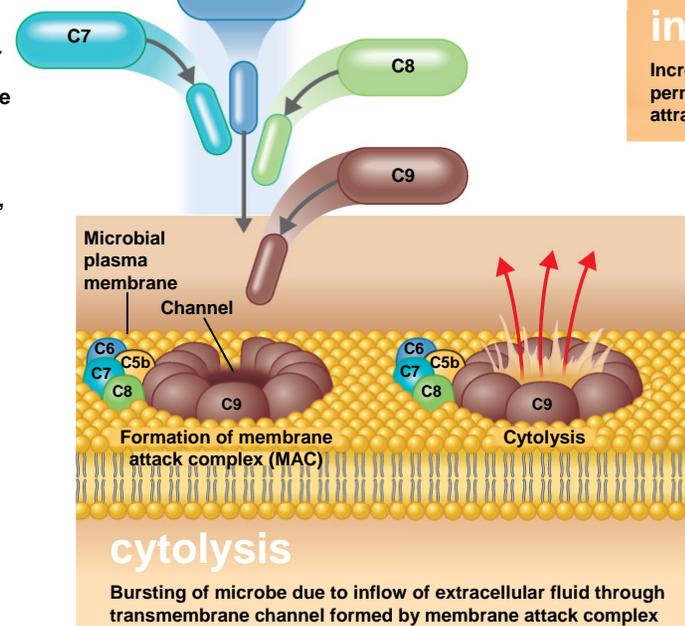

# Outcomes of Complement Activation.

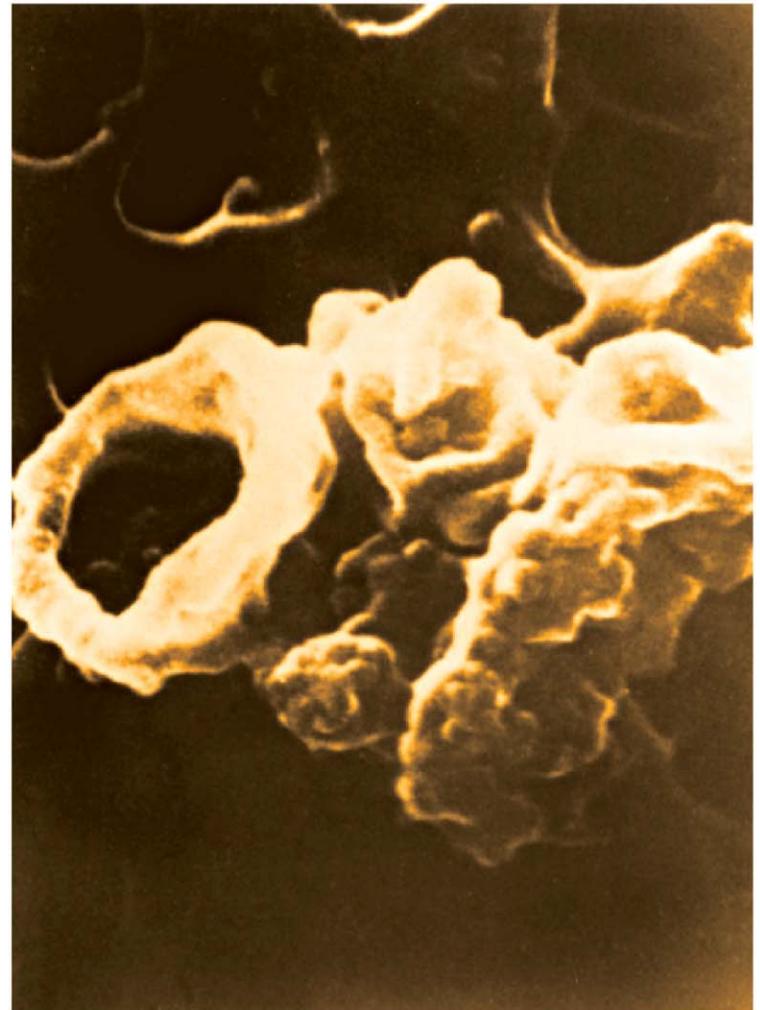

- 1 Inactivated C3 splits into activated C3a and C3b.
- 2 C3b binds to microbe, resulting in opsonization.

- 4 C5b, C6, C7, and C8 bind together sequentially and insert into the microbial plasma membrane, where they function as a receptor to attract a C9 fragment; additional C9 fragments are added to form a channel. Together, C5b through C8 and the multiple C9 fragments form the membrane attack complex, resulting in cytolysis.

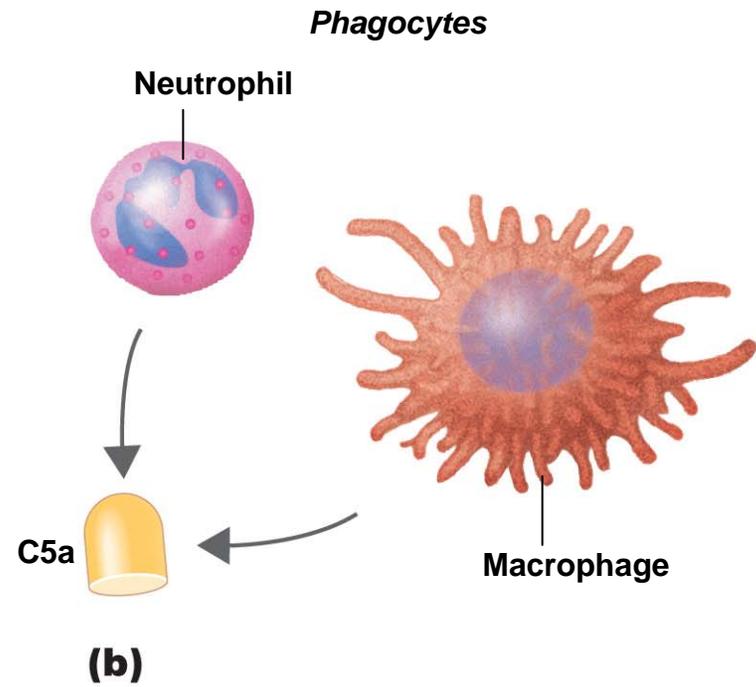

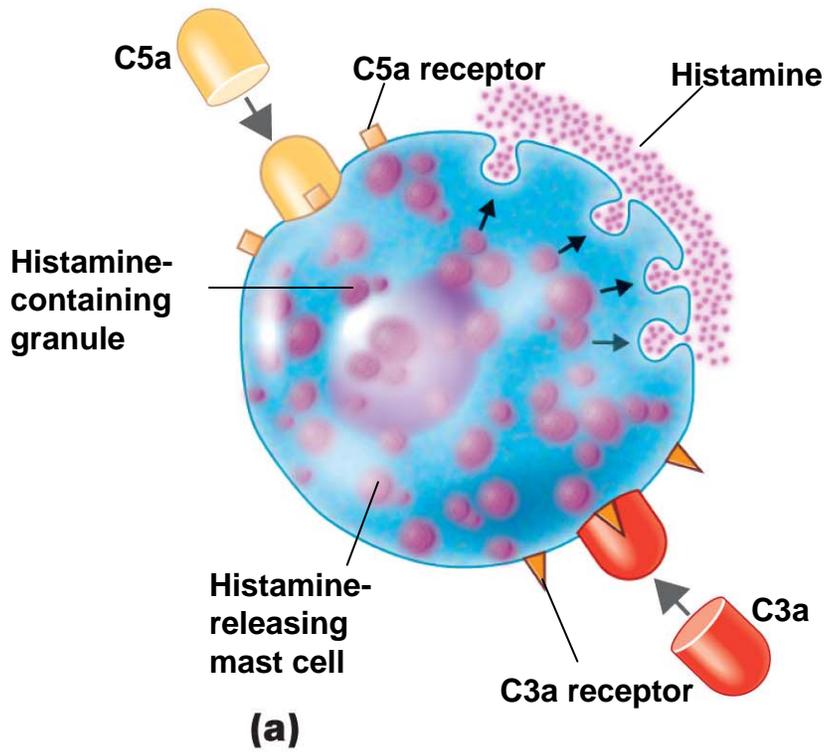

Cytolysis caused by complement.

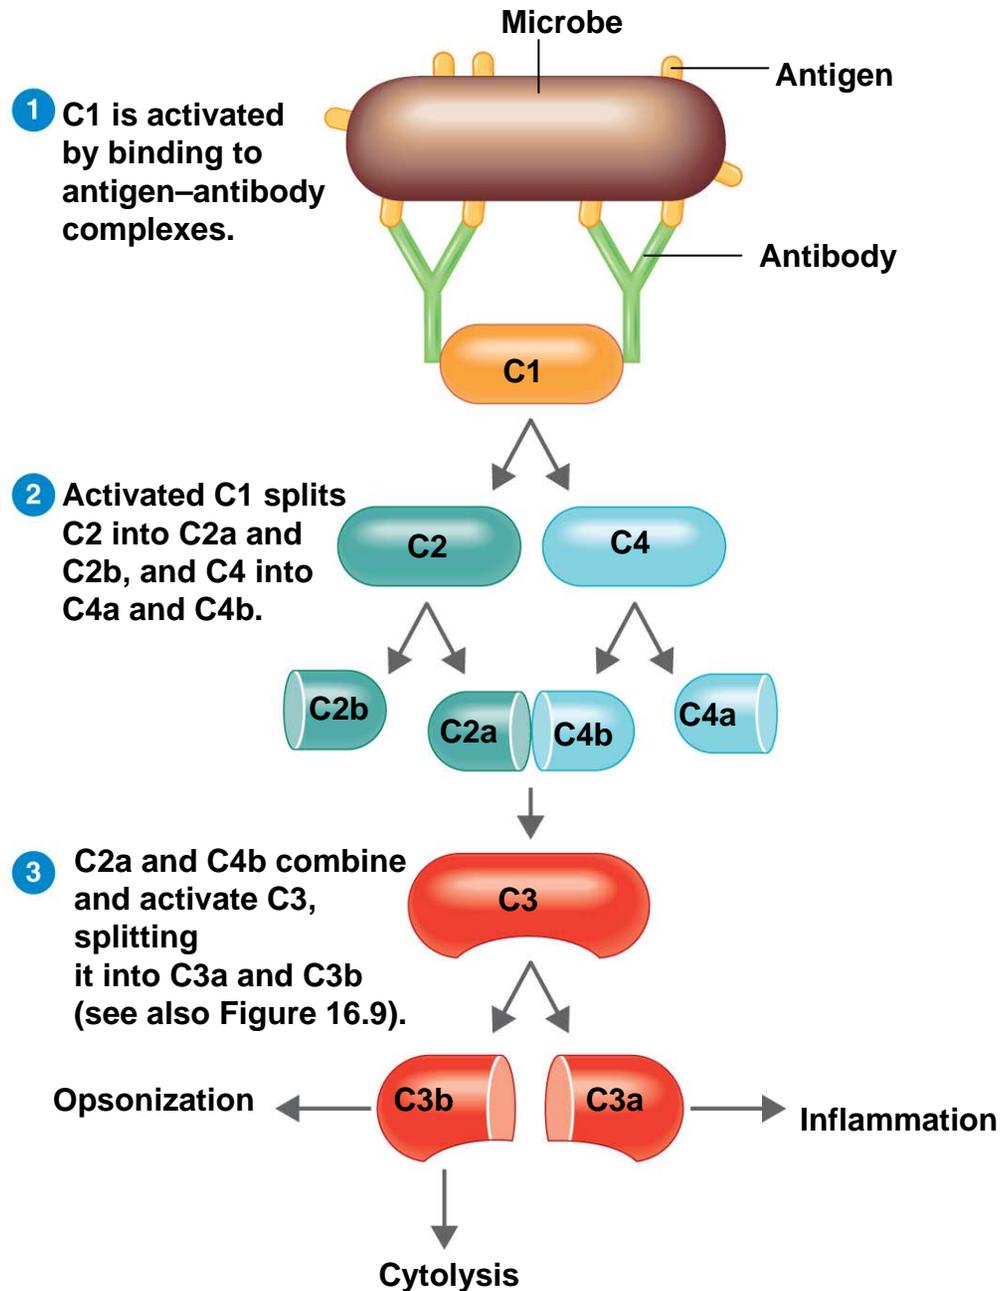

SEM | 2  $\mu$ m

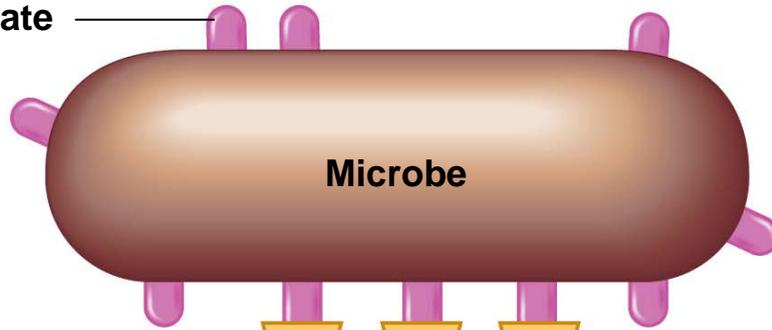

# Inflammation stimulated by complement.

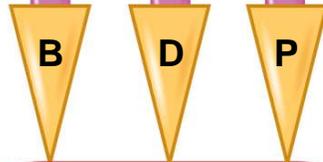

# Classical pathway of complement activation.

Lipid-carbohydrate complex

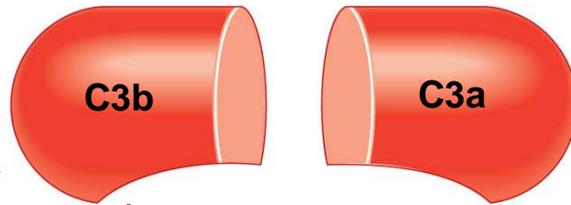

Microbe

Alternative pathway of complement activation.

1 C3 combines with factors B, D, and P on the surface of a microbe.

2 This causes C3 to split into fragments C3a and C3b.

Opsonization

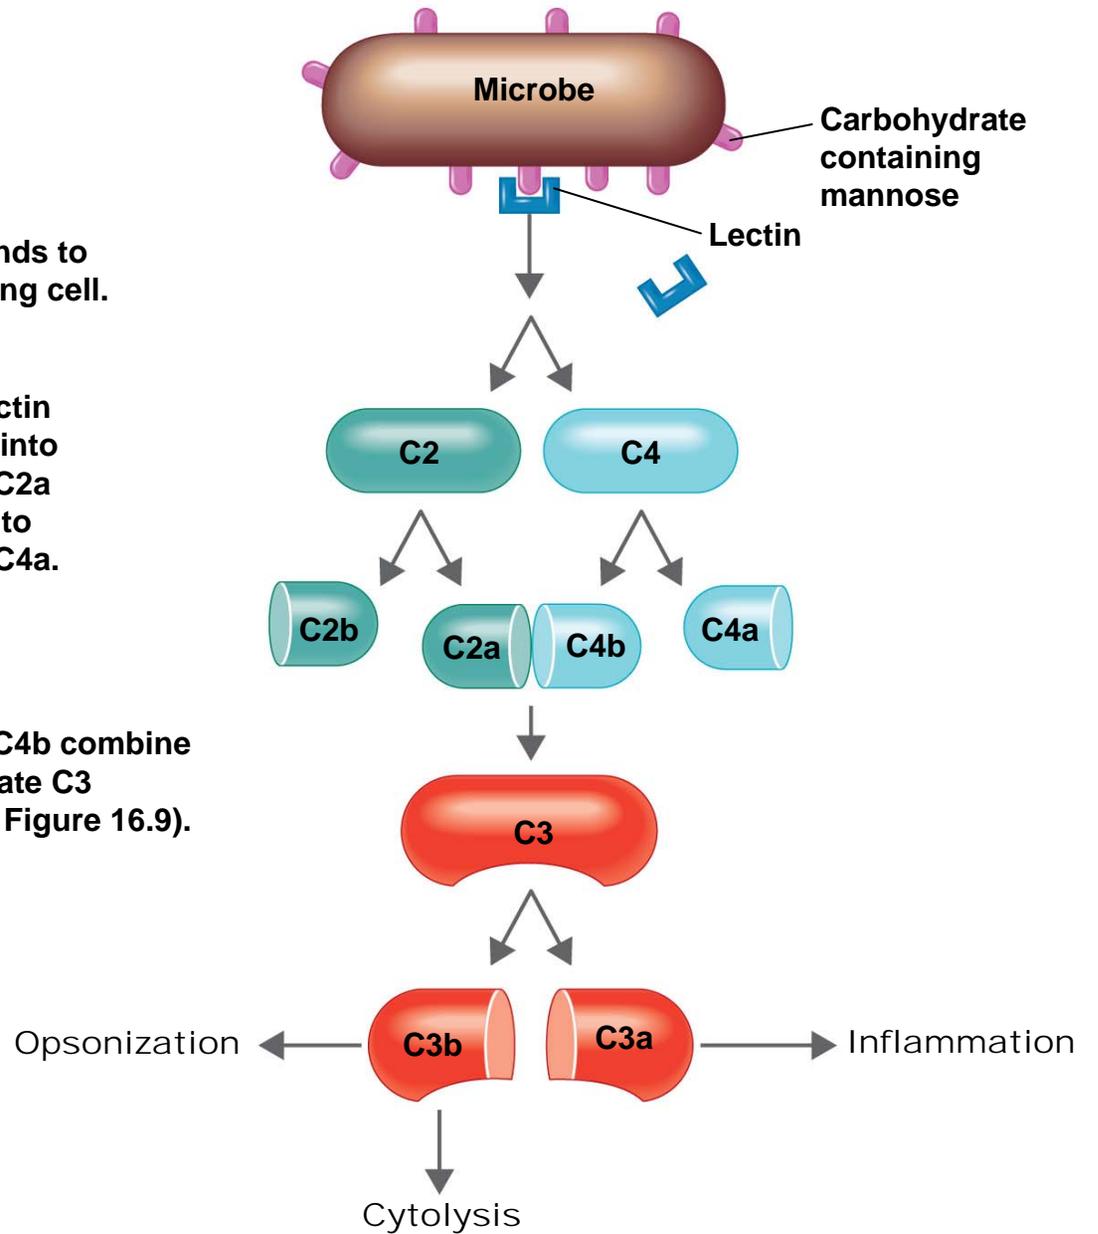

Cytolysis

Inflammation

Key:  B factor  D factor  P factor

# The lectin pathway of complement activation.

- 1 Lectin binds to an invading cell.
- 2 Bound lectin splits C2 into C2b and C2a and C4 into C4b and C4a.
- 3 C2a and C4b combine and activate C3 (see also Figure 16.9).

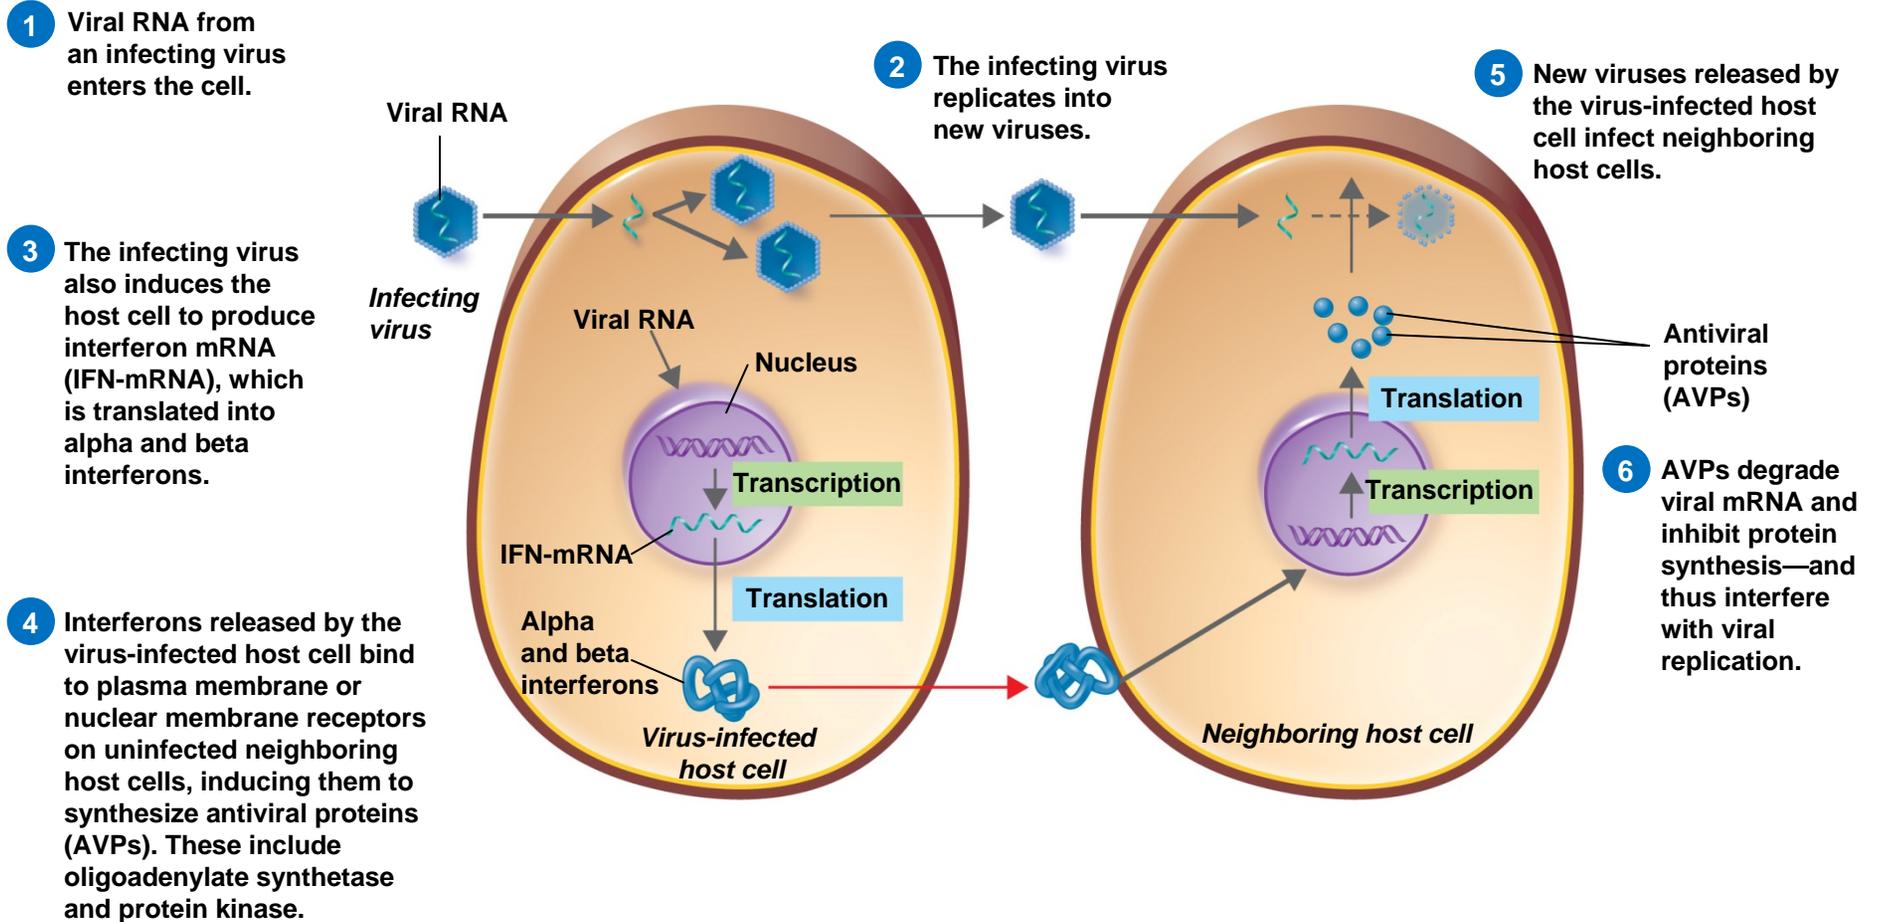

# How Some Bacteria Evade Complement

- Capsules prevent Complement activation
- Surface lipid–carbohydrate complexes prevent formation of membrane attack complex (MAC)
- Enzymatic digestion of C5a

# Interferons (IFNs)

- IFN- $\alpha$  and IFN- $\beta$ : cause cells to produce antiviral proteins that inhibit viral replication
- IFN- $\gamma$ : causes neutrophils and macrophages to phagocytize bacteria

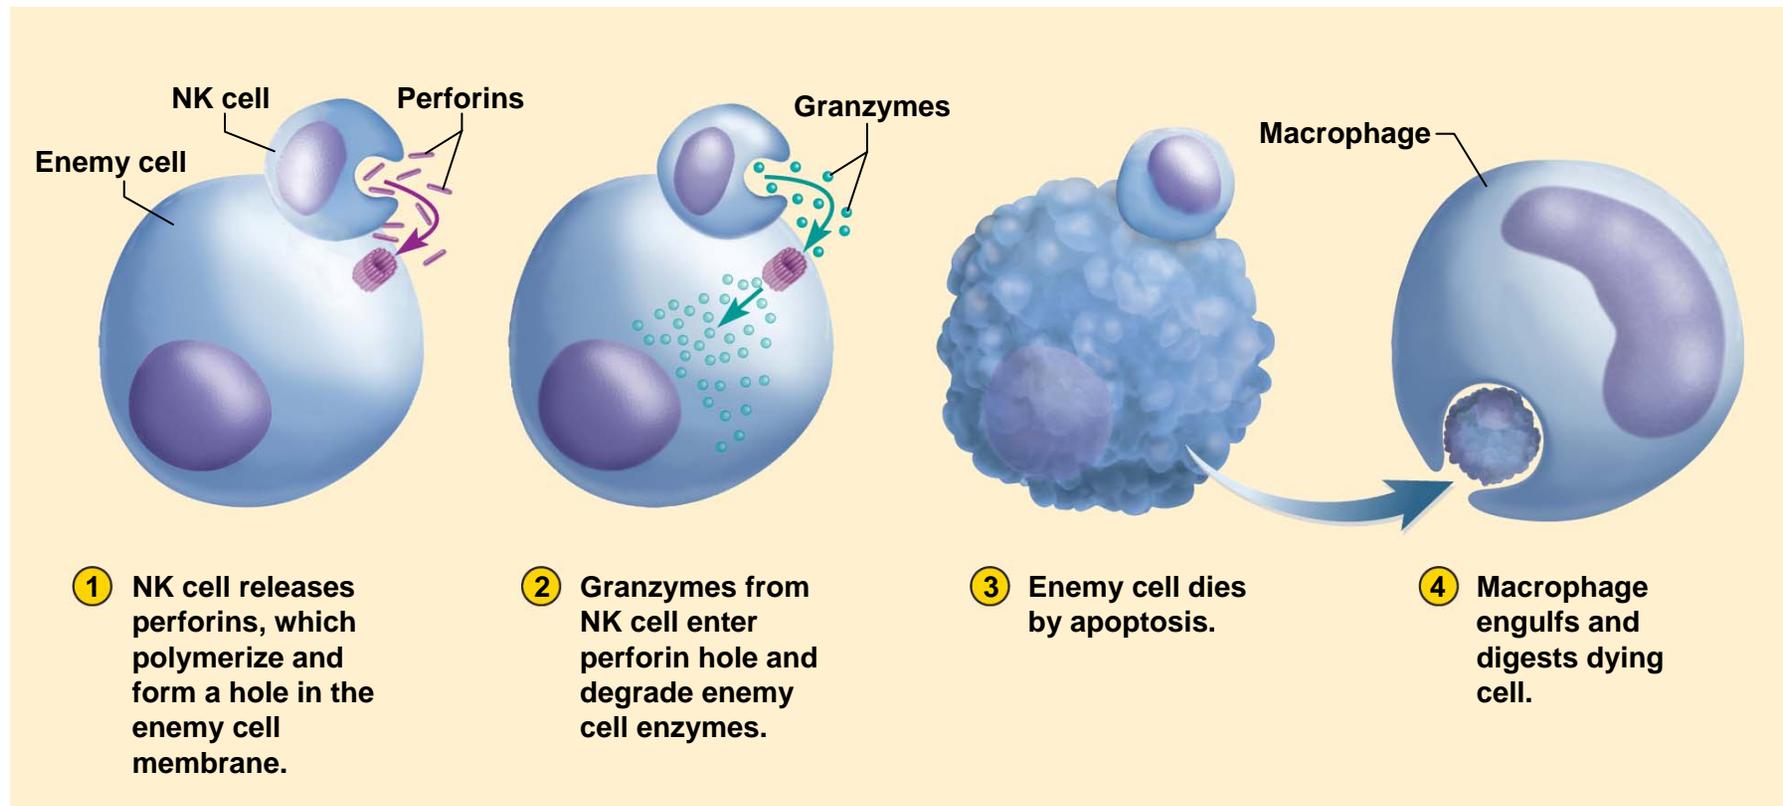

# Antiviral action of alpha and beta interferons (IFNs).

# Natural Killer Cells (NK Cells)

- Type of lymphocyte
- Circulate in blood, lymph, and body tissues
- Kill host cells infected with cancer or virus
- Non-specific reaction using granzymes and perforin
- Call “immune surveillance

# Action of NK cell

Note: same mechanism used by cytotoxic T cells in specific immunity!
