Chapter 18

An Introduction to the Endocrine System

Hormone Chemistry
• **endocrine system** - glands, tissues, and cells that secrete hormones

• **endocrine glands** – organs that are traditional sources of hormones

• **hormones** chemical messengers that are transported by the bloodstream and stimulate physiological responses in cells of another tissue or organ, often a considerable distance away

• **endocrinology** – the study of this system and the diagnosis and treatment of its disorders

---

**Key Steps:**

1. Hormone synthesized by tissue.
2. Hormone released into blood.
3. Hormone circulates within cardiovascular system
4. Hormone leaves blood, diffuse to target tissue’s receptor.
5. Hormone binds to receptor.
6. Hormone changes metabolism of target tissue.
Some Organs Hard to Classify

- Pancreas (mixed gland)
  - Exocrine – digestive enzymes
  - Endocrine – insulin / glucagon

- Hepatocytes (liver cells) defy rigid classification
  - releases hormones
  - releases bile into ducts
  - releases albumin and blood-clotting factors into blood (not hormones)
Comparison of Nervous and Endocrine Systems

• both serve internal communication
  – nervous - both electrical and chemical
  – endocrine - only chemical

• speed and persistence of response
  – nervous - reacts quickly (1-10 msec), stops quickly
  – endocrine - reacts slowly (hormone release in seconds or days), effect may continue for weeks

• adaptation to long-term stimuli
  – nervous - response declines (adapts quickly)
  – endocrine - response persists (adapts slowly)

• area of effect
  – nervous - targeted and specific (one organ)
  – endocrine - general, widespread effects (many organs)
Comparison of Nervous and Endocrine Systems

- several chemicals function as both hormones and neurotransmitters // norepinephrine, cholecystokinin, thyrotropin-releasing hormone, dopamine and antidiuretic hormone

- some hormones secreted by neuroendocrine cells (neurons) that release their secretion into the bloodstream // oxytocin and catecholamines

- both systems with overlapping effects on same target cells // norepinephrine and glucagon cause glycogen hydrolysis in liver

- systems regulate each other // neurons trigger hormone secretion // hormones stimulate or inhibit neurons
Communication by the Nervous and Endocrine Systems

(a) Nervous system

- Neuron
- Nerve impulse
- Neurotransmitter
- Target cells

(b) Endocrine system

- Endocrine cells
- Target cells
- Hormone in bloodstream
Major Endocrine Organs

organs of endocrine system / know these

</tbody>
</table>
• Hormone chemistry.

• What are the different chemical properties of hormones and what are their mechanisms of actions?
• Three Chemical Classes
  
  – **steroids**
    - derived from cholesterol
    - secreted by gonads and adrenal glands
    - estrogens, progesterone, testosterone, cortisol, corticosterone, aldosterone, DHEA, and calcitriol
  
  – **peptides (and glycoproteins)**
    - created from chains of amino acids
    - secreted by pituitary and hypothalamus
    - oxytocin, antidiuretic hormone, releasing and inhibiting hormones, and anterior pituitary hormones
Three Chemical Classes

- monoamines (biogenic amines)
  - derived from amino acids
  - secreted by adrenal, pineal, and thyroid glands
  - epinephrine, norepinephrine, melatonin, and thyroid hormone

- Note: all hormones are made from either cholesterol or amino acids (with carbohydrate added to make glycoproteins).
Hormone Synthesis: Steroid Hormones

- synthesized from cholesterol – differs in functional groups attached to 4-ringed steroid backbone

Cholesterol → Progesterone → Estradiol → Testosterone → Cortisol (hydrocortisone) → Aldosterone
Peptides

- synthesized using same metabolic pathways as any other protein
- first formed as an inactive pre-prohormone
- several amino acids in peptide function as a signal that guides it into cisterna of rough endoplasmic reticulum
- signal peptide removed to form prohormone
- Golgi does final transformation to hormone packaged for secretion
Hormone Synthesis: Insulin

- begins as **pre-proinsulin**, then becomes **proinsulin**

- when **connecting peptide** is removed, two polypeptide chains are formed that make up insulin
Monoamines

• These are synthesized from amino acid

• E.g. /// Melatonin (the hormone released by the pineal gland) is synthesized from the amino acid tryptophan /// transformed into the brain neurotransmitter serotonin which is then transformed into melatonin

• E.g. /// thyroid hormone is composed of 2 tyrosines (tyrosine is an amino acid)
Thyroid Hormone Synthesis (not on exam)

1. Iodide absorption and oxidation
2. Thyroglobulin synthesis and secretion
3. Iodine added to tyrosines of thyroglobulin
4. Thyroglobulin uptake and hydrolysis
5. Release of T₄ and a small amount of T₃ into the blood
**T₃ and T₄ Synthesis** (not on exam)

- Follicular cells
  - absorb **iodide** (I⁻) **ions** from blood and store in lumen as a reactive form of iodine
  - synthesize **thyroglobulin** and store in lumen // forms colloid // contains lots of tyrosine
  - tyrosine and iodine combine to form thyroxine (T₄) bound to thyroglobulin
  - stored in follicle
T₃ and T₄ Synthesis  (not on exam)

- TSH
  - stimulates follicular cells to remove T₄ from thyroglobulin for release into plasma
  - most T₃ is produced in liver or by target cells removing an iodine from circulating T₄
  - 95% T₄ and 5% T₃
Hormone Transport

- **most monoamines and peptides** are hydrophilic // mix easily with blood plasma

- **steroids and thyroid hormone** are hydrophobic
  - Hydrophobic hormones need to bind to *transport proteins* (albumins and globulins which are synthesized by the liver)
  - “bound hormones”
    - have longer half-life
    - protected from liver enzymes and kidney filtration
    - transport proteins protect circulating hormones
    - being broken down by enzymes in the plasma and liver
    - being filtered out of the blood by the kidneys

- only hydrophobic hormones that become unbound are able to leaves capillaries to reach target cell
Hormone Transport

- **thyroid hormone /// exception to the rule /// protein based hormone but binds to three transport proteins in the plasma**
  - albumin, thyretin and TGB (thyroxine-binding globulin)
  - more than 99% of circulating TH is protein bound

- **Some steroid hormones bind to globulins /// transcortin is the transport protein for cortisol**
  - Aldosterone /// short half-life
  - 85% unbound
  - 15% binds weakly to albumin and others
Hormone Receptors

- hormones stimulate **only those cells that have receptors for them**

- **receptors** are protein or glycoprotein molecules: **on plasma membrane**, in the **cytoplasm**, or in the **nucleus**

- receptors act like switches turning on metabolic pathways when hormone binds to them

- usually each target cell has a **few thousand** receptors for a given hormone

- receptor-hormone interactions exhibit **specificity and saturation**
  - specific receptor for each hormone
  - saturated when all receptor molecules are occupied by hormone molecules
Hormone Mode of Action

- hydrophobic hormones
  - penetrate plasma membrane and enter nucleus
  - act directly on the genes changing target cell physiology
  - estrogen, progesterone, thyroid hormone act on nuclear receptors
  - take several hours to days to show effect due to lag for protein synthesis
Hormone Mode of Action

- hydrophilic hormones
  - cannot penetrate into target cell
  - must stimulate physiology indirectly
  - Second messenger systems
Thyroid Hormone

- thyroid hormone enters target cell by diffusion – mostly as $T_4$ with little metabolic effect

- within target cell, $T_4$ is converted to more potent $T_3$

- $T_3$ enters target cells and binds to receptors in chromatin

- activates genes
  - make a muscle protein (myosin) enhancing cardiac muscle response to sympathetic stimulation
  - strengthening heartbeat
Peptides and Catecholamines: Hydrophilic

- hormone binds to cell-surface receptor
- receptor linked to second messenger system on other side of the membrane
- activates G protein which
- activates adenylate cyclase
- produces cAMP
- activates or inhibits enzymes
Other Second Messengers

- diacylglycerol (diglyceride) second-messenger system
- inositol triphosphate second-messenger system
- act on cell metabolism in a variety of ways
Enzyme Amplification

- Hormones are extraordinarily potent chemicals.
- One hormone molecule can trigger the synthesis of many enzyme molecules.
- Very small stimulus can produce very large effect.
- Circulating concentrations very low.
Modulation of Target Cell Sensitivity

- target cell sensitivity adjusted by changing the number of receptors

- **up-regulation** means number of receptors is increased // sensitivity is increased

- **down-regulation** reduces number of receptors
  - cell less sensitive to hormone
  - happens with long-term exposure to high hormone concentrations

  - bind to other receptors

  - converted to different hormone
Hormone Interactions

- most cells sensitive to more than one hormone and exhibit interactive effects

- synergistic effects
  - multiple hormones act together for greater effect // synergism between FSH and testosterone on sperm production

- permissive effects
  - one hormone enhances the target organ’s response to a second later hormone // estrogen prepares uterus for action of progesterone

- antagonistic effects
  - one hormone opposes the action of another // insulin lowers blood glucose and glycogen raises it
Hormone Clearance

- hormone signals **must be turned off** when they have served their purpose

- most hormones are **taken up and degraded by liver and kidney** // excreted in bile or urine

- metabolic clearance rate (MCR)
  - rate of hormone removal from the blood
  - **half-life** - time required to clear 50% of hormone from the blood
  - faster the MCF, the shorter is the half-life
